

beginning of April. While the Magnetawan River is less developed than the Muskoka River watershed, defined areas of the Township of Armour, the Township of Ryerson, and the Village of Burks Falls were significantly affected by flooding in the spring of 2019. The small village of Katrine, one of the areas hardest hit in the Township of Armour, is built on a floodplain at the mouth of Doe Lake, where approximately 50 homes were flooded.

4.5 Flooding in the County of Haliburton

The County of Haliburton includes the headwaters of the Trent Severn Waterway (TSW) system, which controls water flows and levels for more than 18,000 square kilometres of the Trent Severn Watersheds. The Trent River basin encompasses 218 lakes in the Haliburton Highlands region, 37 of which are directly controlled by TSW dams. There are some 600 named lakes in Haliburton County with significant waterfront property ownership, including a notable number of water-access only properties.

Watersheds represented in Haliburton County include—the Black River watershed that flows south and west to the Muskokas; the Burnt River watershed; the Gull River watershed (which encompasses the Burnt River system); and the Nogies Creek, Eels and Jack Lake watershed.

As experienced in other regions of Ontario, Haliburton County has been experiencing significant flooding, most notably in 2013, 2016, 2017 and 2019. Declarations of Emergency were declared in 2013, 2017 and 2019, with near misses in 2016 and 2018.

4.6 Flooding along Lake Ontario and the St. Lawrence River

4.6.1 Flooding Conditions in 2019

Following an extended period of below average water levels from 1999 to about 2013, all Great Lake water levels were well above their average in 2019. Lake Superior, Lake St. Clair, Lake Erie and Lake Ontario all exceeded record highs in May, while Lake Huron rose to within one centimetre of the previous record in July.

Significant precipitation and snowmelt around the Lake Ontario basin, combined with record inflows from Lake Erie, set a new record for total water inflows, or supply, to Lake Ontario for the month of May, exceeding the previous record set in 2017. Total inflows in May 2019 were the second highest inflows of any month of the year dating back to 1900. Total inflows to Lake Ontario in June were the second highest on record. From January to June 2019, the six-month combined total inflows were the wettest January to June period on record due to a combination of record inflows from Lake Erie and wet conditions on and around Lake Ontario itself. Downstream of the lake, flows

from the Ottawa River emptying into the lower St. Lawrence River also set a new record high during the spring freshet 2019. The flows in May 2019 exceeded the previous monthly record in 1974 by more than 1,000 cubic metres per second.

As described by the International Joint Commission's (IJC) International Lake Ontario-St. Lawrence Board, Lake Ontario was caught between a flooding Lake Erie upstream and a flooded lower St. Lawrence River downstream. Upstream, Lake Erie water levels were exceeding historic record highs by the beginning of May. Downstream, several months of wet weather followed by heavy rains and snowmelt over late April and early May caused record Ottawa River flows, resulting in severe flooding along the Ottawa and lower St. Lawrence River. This combination of record high inflows from Lake Erie and above average precipitation across the Lake Ontario and Ottawa River basins was the main driver of Lake Ontario-St. Lawrence record high water levels in 2019. Lake Ontario water levels ultimately reached 75.92 metres in early June, exceeding the record daily peak of 75.88 metres reached previously in late May 2017.

Water levels of Lake Ontario change in response to the difference between the supply (total inflow) it receives and its outflow. While outflows are controlled by the Moses-Saunders Dam, inflows are uncontrolled. While the IJC's Plan 2014, brought into effect in 2017, regulates flows through the Moses-Saunders Dam (outflows), inflows are uncontrolled. While increasing outflows through the Moses-Saunders dam can help reduce water levels in Lake Ontario, the amount of control this structure has over water levels in Lake Ontario is very limited, as there are physical limits to the amount of water that can be released. Larger releases, while they may reduce flooding in Lake Ontario, can have drastic impacts downstream. Increasing outflows enough to reduce flood levels in Lake Ontario by one centimetre in a week will result in increasing flood levels below the dam in Montreal by 10 centimetres.

Throughout April and May 2019, the IJC's International Lake Ontario-St. Lawrence Board continued to regulate Lake Ontario outflows by the maximum flow limits prescribed by Plan 2014. In June, as Ottawa River flows began to moderate below their record highs, the Board rapidly increased outflows from the Moses-Saunders Dam to provide relief from shoreline flooding on Lake Ontario. Outflows were ultimately increased to the maximum sustained flow on record, as the Board was now undertaking major deviations from the plan to provide relief from shoreline flooding on Lake Ontario. These outflows reached 10,400 cubic metres per second, equivalent to the record high outflows released for several weeks in the summer of 2017. These major deviations of flow are significant departures from the outflows prescribed in Plan 2014; however, the IJC was doing so in response to extremely high Lake Ontario levels and in accordance with IJC policies. In Ontario, flooding occurred around Lake Erie, Lake Ontario and the upper St. Lawrence River, especially during periods of active weather.

From media reports, Prince Edward County, the Bay of Quinte, Toronto Island, Municipality of Clarington, Brighton, and the Thousand Islands shoreline area in the upper river, among other areas, experienced flooding.

4.6.2 Comparison to Flooding Conditions in 2017

The causes of record high Lake Ontario water levels in 2017 and regulation of outflows under Plan 2014 were studied and reported on by the Board (see the IJC report titled: “Observed Conditions and Regulated Outflows in 2017,” May 25, 2018, https://ijc.org/sites/default/files/2018-08/ILOSLRB_FloodReport2017.pdf). The Board attributed the extreme high levels mainly to record precipitation received across the Lake Ontario-St. Lawrence River basin, noting that wet weather was also experienced upstream in the Lake Erie watershed. Lake Ontario water levels rose rapidly, setting record highs by the end of May. In response, in all but three weeks of the year, outflows from the lake were determined by either the maximum flow limits set by Plan 2014 or by deviations from Plan 2014. The Board concluded that Plan 2014 did not cause the high levels in 2017 or contribute to them in any significant way.

Flooding in 2017, among other impacts, were reported on by the IJC’s Great Lakes-St. Lawrence River Adaptive Management Committee as part of their ongoing evaluation of the IJC’s regulation of lake outflows in the Great Lakes (see the IJC report titled: “Summary of 2017 Great Lakes Basin Conditions and Water Level Impacts to Support Ongoing Regulation Plan Evaluation,” November 13, 2018, https://ijc.org/sites/default/files/2018-11/GLAM_2017_MainReport_FINAL-20181129_2.pdf). The Committee evaluated the impacts on multiple interests, including flooding, from a variety of sources. They noted, however, that much of the quantitative economic and environmental data was not available at the time of reporting.

Impacts to coastal properties in 2017 were reported as widespread, with reports of flooded homes, roads, driveways, trails, lawns, emergency response, and extensive sandbagging efforts to protect houses and properties. In Ontario, flooding of residential property and buildings along the Lake Ontario shoreline was observed with particularly hard-hit areas including portions of Toronto Island, Clarington, Brighton, and Prince Edward County. On the upper St. Lawrence River, shoreline flooding was observed particularly in the Thousand Islands area. From the IJC’s report, Figure 5-25 highlights the percent of shoreline survey respondents that indicated flooding impacts. In Ontario, along the lake shoreline, a local State of Emergency was declared for a portion of the Municipality of Clarington shoreline as well as all of Prince Edward County. The Mohawks of the Bay of Quinte also declared an emergency for their territory in response to high water levels.

4.7 Flooding along Lake Erie and Lake St. Clair Shorelines

Since March 2019, water levels in Lake Erie and Lake St. Clair have remained above locally determined Flood Watch thresholds, with monthly mean lake levels in Lake Erie and Lake St. Clair reaching all time highs in July 2019. Lake Erie is approximately 84 centimetres above long-term monthly average lake levels (or 13 centimetres above previous highs in 1986 and 35 centimetres higher than July 2018). Lake St. Clair is approximately 86 centimetres above long-term monthly average lake levels. This is 10 centimetres above previous 1986 highs and 35 centimetres higher than July 2018.

These record levels have resulted in the Windsor Essex region being under an Extended Flood Watch for more than six months. Similarly, the Lower Thames Valley Conservation Authority has issued 50 flood bulletins (Watershed Conditions Statements/Flood Watches/Flood Warnings) warning shoreline residents of potential flood events so far this year (2019).

Portions of Essex Region, in the Southeast Leamington area between Hillman Marsh and Point Pelee, lie behind earthen dikes built in the late 1800s that have been “spot-repaired” sporadically over time as emergencies required. Approximately 400 homes and 2,100 hectares of farmland are, in some instances, 3 to 3.35 metres below Lake Erie water levels.

While lake levels are currently undergoing seasonal decline, they remain above previous 1986 record levels, meaning these declines have not resulted in any reduction in the level of flood/erosion risk in the region. Making matters worse, fall rain events, wind and winter ice is expected to result in further flooding and erosion.

4.7.1 2019 Flooding

Flooding and erosion along the Lake Erie shoreline resulting from high water levels has had, and in most cases continues to have, significant impacts on residents, businesses and infrastructure.

Three sections of roads have been closed along Lake Erie in Chatham-Kent (total length of road closed is 9.6 kilometres). Similarly, LaSalle and Kingsville have closed sections of road due to high water levels.

High water levels have closed marinas in Windsor and Lakeshore, closed waterfront trails in Windsor, and closed sections of the Holiday Beach Conservation Area and Tremblay Beach Conservation Area.

Residents along the Lake Erie Shoreline between Point Pelee National Park and the Town of Wheatley experienced 10 flood events between March 2019 and August 2019.

This area was developed on a naturally eroding clay shoreline. Therefore, even without the existing development, they would continue to erode. Under the current condition (high lake level), wave action is causing erosion at the shore. Under low lake levels, the erosion is happening on the clay bottom as the waves attack the surf zone.

Shoreline protection structures (sheet pile walls and armour stone breakwalls/revetments) have been used in some areas to try and slow down erosion rates in front of the shoreline protection. However, these structures do not stop erosion of the lake bottom in front of the structures, which results in a deeper and deeper nearshore lake bottom slope. This has allowed larger waves and waves with greater energy to impact the shoreline. In the end, the shoreline protection constructed to reduce the hazard is progressively making it worse. As a result, the flood hazards are getting worse with each passing storm.

Numerous homes and properties have suffered and continue to suffer from flooding with limited access into and out of the community. Some of these areas are not municipally serviced and are sitting in water, which results in failing septic systems, mould and related health and safety and structural concerns, in addition to the physical and mental health effects associated with these conditions.

Current high water conditions have caused significant damage across the shoreline. High waters have also prevented many repairs leaving existing development exposed to both erosion and flood hazards.

With high water levels, lake waves have created a 100+ metre breach in Hillman Marsh Barrier Beach, posing significant risk to inland dikes, which are now exposed to direct wave attack. The inland dikes are now holding back high water levels and over an extended period of time, which they were not constructed to withstand. Inland communities protected by the flood protection dike are also at risk of flooding under this condition.

The Marentette breakwater breached and exposed the interior dikes to open lake wave conditions, which this system was not designed to withstand. Some nominal repairs have proceeded through the provisions of the *Drainage Act*, but these repairs are essentially a temporary fix.

Large blocks of peat continue to be eroded out of the marsh areas in Leamington and Rondeau Bay, with the most recent evidence of this occurring in late summer 2019.

Due to sediment balance issues—a result of shoreline hardening—the barrier beach that forms the southwestern barrier within Rondeau Bay has now been removed for approximately 100 metres. This allows Lake Erie waves to enter Rondeau Bay, putting

the low-lying community of Shrewsbury and 470 homes at risk. Continuing and long-term future flooding is anticipated based on present conditions and climate change forecasts.

A State of Emergency was declared along Erie Shore Drive on August 27, 2019, due to significant flooding caused by high winds (peaked at 35 kilometres per hour) and rain. There are 123 homes at risk along Erie Shore Drive, with 35% being permanent residents. The event resulted in significant damage to 12 homes, the roadway, supporting slope, drain and three breakwalls.

A voluntary evacuation took place in a localized area of Erie Shore Drive, comprising 50 homes. Electricity and natural gas services were shut off where there was a safety risk. The water pressure in the water main (under Erie Shore Drive) that provides drinking water to the community of Erieau was reduced due to fears of failure. In the short time period during and around the event, the municipality shored up the roadway and drainage works.

4.7.2 Erosion

While the flood issues are significant, they cannot be isolated from erosion on the Great Lakes. Many of the areas with the highest flood risks also feature a significant long-term erosion rate. This includes Marentette to Wheatley and Erie Shore Drive and many high bluff areas. In keeping with the 1990s Technical Guide, new development has been allowed to be located as close as possible to shoreline hazards, once the landward limit of the erosion hazard is applied. However, due to climate change, the risk profile is changing. Reductions in lake ice have already and will continue to expose the shorelines to higher amounts of wave energy/erosion. Landowners who thought they were 100 years away from erosion hazards might now only be 50 years away, and significant lengths of municipal infrastructure (roads and utilities) are at risk of failure.

Shoreline erosion on Pelee Island is particularly concerning because it has washed out sections of roadway that provide ingress/egress for residents. Bluff failures have occurred in 2019 related to the erosive effects of the high waters. These failures have impacted existing development with at least one home within 1.5 metres from the precipice. These types of failures are expected soon even as water recedes in the region, as the erosive effects have already occurred at the toe of these bluffs.

The Municipality of Chatham-Kent has closed a significant portion of Talbot Trail (West) (length of road closed is 3.8 kilometres). The road was closed due to erosion on the south side of the road (rotational failure). The solution will require a high level of investment estimated at \$640 million up front and \$12 million per year in maintenance costs.

4.7.3 Recent Severe Rain Events

Risks of flooding in southwestern Ontario are not only a result of high lake levels.

In September 2016, Windsor, Tecumseh and Lakeshore were impacted by a severe and isolated rain event that tracked from the northwest, dumping over 200 millimetres of rainfall in six hours, causing flooding in thousands of urban area basements.

In August 2017, a similar system tracked out of the southwest that formed two distinct storms dumped 146 millimetres of rainfall in less than three hours, which followed a 100-millimetre rainfall earlier. The storm total of 246 millimetres in less than six hours surpasses all accepted design standards. This event exceeded \$300 million in insurable losses.

Because both Essex Region and Lower Thames Valley are low lying, high lake/river levels mean that water from stormwater and drainage systems has no place to go.

For example, 30,000 residents living in parts of the Town of Lakeshore, the Town of Tecumseh and the City of Windsor are fully urbanised centres that exist within Lake St. Clair's historic flood extent. Pumping systems that provide for drainage are now regularly overcome by rainfalls that exceed acceptable design standards. These areas have protection systems to prevent lake flooding (either berms or pumping schemes); however, record lake level elevations are challenging the existing protection systems. Any measurable rainfall, such as those events that happened in 2016 and 2017, will cause significant flooding, especially in the urban centres.

4.8 Other Notable Recent Flooding Events

While flooding in spring 2019 resulted in significant damages to many parts of Ontario, several other recent flood events were also brought to my attention during the review. I've noted some of these other recent flood events in this section for the purpose of demonstrating that the flooding that occurred in 2019 does not appear to be an isolated event. Again, this section is not meant to provide an exhaustive account of notable flooding events in Ontario's recent history— an account of that nature was outside the scope of my assignment. However, I felt it important to include some of these events to help demonstrate that flooding is a common occurrence in Ontario and something that can occur at any time of the year.

4.8.1 Recent Flood Events in the City of Toronto

Over 2.7 million people live in the City of Toronto with nearly six million people living in the Greater Toronto Area (GTA). While 2019 was not a significant year for flooding in

Toronto when compared to other areas, significant events and associated impacts have occurred there in the past and are worth noting as part of this report.

With drainage areas ranging from 38 square kilometres for the Carruthers Creek to 900 square kilometres for the Humber River, watersheds within the City of Toronto tend to be relatively small. These small drainage areas, with short stream lengths and highly urbanized (impervious) surfaces, leave little lead time between rainfall and flood impacts. Year-round flood threats include ice jams in the winter, snowmelt in spring, unpredictable thunderstorms in the summer, and hurricane remnants in the fall.

While land use planning has effectively reduced risk in greenfield areas, many neighbourhoods were historically settled near rivers prior to floodplain management. Examples include old downtowns in Brampton, Bolton, Unionville and Stouffville. There are 41 Flood Vulnerable Clusters (areas where there is a high concentration of buildings in the floodplain) within the jurisdictional area managed by the Toronto and Region Conservation Authority (TRCA) alone.

The most severe flooding on record in Ontario occurred in October 1954, when Hurricane Hazel passed over the Toronto area. Eighty-one lives were lost and damages were estimated at \$25 million (in 1954 dollars). TRCA's recent Flood Risk Assessment study estimates that if Hurricane Hazel were to occur today, it could result in almost \$3 billion in property damages, business disruption and population displacement. While Hurricane Hazel-type storms remain a possibility that must be prepared for, recent events have shown that significant damages and disruption can also occur from significantly smaller events.

On July 8, 2013, a severe thunderstorm dropped more than 120 millimetres of rain over parts of the GTA during the afternoon rush hour, causing roughly \$1 billion in insurable losses and stranding thousands of commuters, including over 1,400 passengers who needed to be rescued from a GO train marooned in floodwaters from the nearby Don River.

In the spring of 2017, water levels in Lake Ontario reached levels higher than ever recorded. The impact was significant on Toronto Islands, home to over 800 residents, almost 30 businesses and two schools. The islands' parks experienced significant shoreline erosion, damage and debris accumulation. Direct and indirect damages to the City of Toronto due to the closing of Toronto Island Park were estimated to be \$8 million for the 2017 event. In 2019, water levels rose even higher than in 2017, though preventative measures helped to keep the islands open. In 2019, the newly reached record levels were maintained for nearly four weeks. A full accounting of damages from the 2019 levels is still underway.

On August 8, 2018, a highly localized “ninja” storm dumped over 100 millimetres of rain in less than two hours. This storm was not forecast and was so localized that its track evaded detection by TRCA’s real-time precipitation gauges. Flows in Black Creek in the Rockcliffe neighbourhood, a highly flood vulnerable area, rose over two metres in 75 minutes, spilling into nearby properties and stranding two men in an elevator when they attempted to retrieve their vehicles from underground parking. They were rescued by first responders just in time.

On March 15, 2019, as late winter rainfall and snowmelt raised flows in rivers, an ice jam developed in the Town of Caledon, spilling into the Bolton Core neighbourhood. As floodwaters rose through the evening, over 80 homes were evacuated, of which 30 experienced direct flood impacts. The jammed ice had to be manually removed using excavators.

4.8.2 Recent Flood Events in the Grand River Watershed

The Grand River lies at the heart of one of the fastest growing regions in Ontario; however, the watershed faces challenges brought on by intensive population growth, extensive agriculture and climate change. Warmer air and water temperatures, bigger rainstorms and dramatic changes in weather patterns pose new challenges in managing floods, improving water quality and securing water supplies for municipalities, farmers, industry and the natural environment.

Flooding in the Grand River watershed has many causes including:

- Rapid snowmelt over a short period of time;
- Combined rainfall and snowmelt;
- Localized ice jam flooding;
- Moderate rainfall on saturated or frozen ground;
- Extreme localized rain (severe cellular storms, convective thunderstorms or lake breeze events);
- Severe widespread rain (tropical storm remnants or large low pressure systems); and
- Lake Erie surge (shoreline).

While there is seasonality associated with certain types of flooding in the watershed, the risk of riverine flooding remains relatively consistent throughout the year. Compounding challenges associated with riverine flooding, Lake Erie presents additional challenges through lake surge flooding, shoreline erosion and the influence of lake breezes (wind blowing from the water to the shore).

Large floods tend to happen on a cyclical basis in the watershed and trends show they occur in clusters. Data indicates there were clusters of large floods in the late 1940s, mid-1970s, early 2000s, late 2000s, and more recently 2017 and 2018.

In June of 2017, an unforecasted rainfall event caused significant flooding in the communities of Grand Valley, Drayton, West Montrose, Conestogo Cambridge-Preston and Glen Morris. More than 125 millimetres of rain fell across the northern portion of the watershed in the span of a few hours, resulting in the highest flows seen in the Grand River through Cambridge since the May 1974 benchmark flood event. Reports (unconfirmed) of several million dollars in damage resulted from this event.

The highest single-day rainfall event ever recorded in the Grand River watershed occurred in February 2018 and resulted in near floods of record that were further complicated by major ice jams in multiple communities. More than 5,000 residents in Brantford were evacuated due to overtopping of the dike system due to ice jams in that community. Dams owned and managed by the Grand River Conservation Authority helped reduce flows in the order of 40 to 50% downstream of the major reservoirs; however, significant transportation disruptions (road/bridge closures) still occurred due to ice impact. Municipal flood damages in Cambridge and Brantford associated with this event were reported to be in excess of \$5 million. Damage incurred by individual property owners and businesses is unknown.

Snowmelt and ice jams in February 2019 resulted in the second highest community ice jam (West Montrose) identified in records dating back to 1967. This event was only exceeded by an event in February 1981.

Chapter 5

Ontario's Approach to Managing Flood Risk

Ontario's current approach to managing risks associated with flooding is based on the five core components of emergency management: 1) Prevention; 2) Mitigation; 3) Preparedness; 4) Response; and 5) Recovery. Management is achieved through the use of a series of provincial acts, regulations, policies and technical guides that are implemented through partnerships with a number of provincial ministries, municipalities, First Nations and conservation authorities.

The objectives with this approach are to save lives and money, protect property, public health and the environment, maintain economic stability, help assure the continuance of critical infrastructure, and reduce social disruption associated with emergencies.

5.1 The Five Core Components of Emergency Management

5.1.1 Prevention

Prevention includes actions taken to prevent flood-related emergencies or disasters from occurring, and includes land use planning and regulatory restrictions to keep development out of the floodplains and other hazardous areas. While we cannot prevent flooding from occurring, keeping people and property out of flood-prone areas helps ensure naturally occurring flood events do not result in local emergencies.

As an overall principle for flood management, the MNRF prioritizes the use of non-structural and land use planning measures as its preferred approach to manage flood risks. This includes the identification of hazardous areas, including floodplains. Municipalities can then plan to prohibit/limit activities, including development, in these areas. The main legislative tools used to support this approach include the *Planning Act* together with the Provincial Policy Statement and the *Conservation Authorities Act*.

5.1.2 Mitigation

Mitigation includes actions taken to reduce the effects of flooding, and includes the use of structural measures and floodproofing standards to protect development. Structural measures can include dams, dikes, channels, diversions and other flood control works. Floodproofing standards can include a combination of measures incorporated into the basic design and/or construction of buildings, structures or properties to reduce or eliminate flooding hazards, wave uprush and other water-related hazards, such as constructing the lowest occupancy floor of dwellings, water shut off and electrical control panel above the design flood level, and having water resistant electrical systems.

5.1.3 Preparedness

Preparedness includes the use of flood forecasting and warning to assess the potential for flooding, predict when and where flooding will occur, and help ensure an effective response (e.g. any required evacuations or mitigative activities).

The Province conducts flood forecasting and warning via the MNRF's Surface Water Monitoring Centre, which monitors weather, rainfall and stream flows, and provides advisories and a suite of products and tools (e.g. weather panels, snow survey reports) to conservation authorities (CAs), municipalities and MNRF district offices on flood potential. The monitoring of flood conditions occurs seven days a week, and the Province is able to contact CAs and other stakeholders immediately with updates.

Local scale flood forecasting and warning is provided by MNRF district offices and conservation authorities. Many of the CAs conduct more detailed flood forecasting and warning for their respective jurisdictions.

5.1.4 Response

Response includes actions taken to respond to flood emergency, such as the use of emergency services (e.g. providing sandbags, community evacuations, etc.) to protect people and property during flood events. Response can also include training for emergency response staff and meeting with stakeholders/partners to ensure an effective response. It also includes providing logistical support and social and health services.

The *Emergency Management and Civil Protection Act* (EMCPA) establishes Ontario's legal basis and framework for managing emergencies (see Section 5.2.4). It does this by defining the authority, responsibilities and safeguards accorded to provincial ministries, municipalities and specific individual appointments, such as the Commissioner of Emergency Management.

5.1.5 Recovery

Recovery includes actions taken to recover from a flood emergency, such as the use of disaster financial assistance to restore property to pre-flood conditions.

Provincially, financial assistance is delivered through two programs—the Disaster Recovery Assistance for Ontarians (DRAO) program for homeowners, tenants, small owner-operator businesses and farms, and not-for-profit organizations; and the Municipal Disaster Recovery Assistance (MDRA) program for municipalities. These programs provide funds for eligible expenses following a natural disaster to help Ontarians and municipalities recover from extraordinary costs. The DRAO program

covers 90% of eligible costs (subject to a \$500 deductible and a cap of \$250,000). Since the program launched in 2016, it has been activated for 28 events in 68 municipalities, with \$11 million in assistance paid. The MDRA program is based on a sliding-scale cost-sharing formula. Since the program launched in 2016, it has been activated for 16 municipalities, with assistance payments of \$4 million.

Municipalities can access the MDRA program when eligible disaster-related costs reach 3% of the municipality's Own Purpose Taxation levy. Due to the eligibility threshold based on municipal financial capacity, the program is accessed most frequently by small municipalities with a correspondingly small tax base.

The federal government provides funding to provinces and territories for disaster response and recovery costs under its Disaster Financial Assistance Arrangements (DFAA) program. Under this program, the federal government shares costs with provinces and territories based on a sliding-scale per capita formula. Ontario, as the largest province, has the highest threshold for federal funding and consequently is eligible for the DFAA much less frequently than most other provinces. Based on the current formula (which is adjusted for inflation each year), Ontario could access federal funding under DFAA only in the event of a disaster costing the province in excess of \$46.2 million.

Ontario has only qualified for DFAA three times in the relatively recent past—for the 1998 ice storm, the 2004 Peterborough flood and the 2013 ice storm. As a result, disaster financial assistance costs associated with recovery are funded almost entirely by provincial coffers, although the overall financial burden for disasters is borne to a great extent by municipalities and property owners as well.

5.2 Acts, Regulations, Policies and Technical Guides

Ontario's preventative approach of directing development away from floodplains and other hazardous areas is highly effective in preventing property damage. Property damage associated with the same storm event are often exponentially lower in Ontario than they are in Great Lakes states, with the differences in losses primarily attributed to differences in floodplain management policies and approaches.

Provincial policies have been shown to reduce capital and operating costs associated with managing flooding and other natural hazards, reducing pressure on provincial and municipal infrastructure debts. The existing policies have been estimated to reduce costs associated with ongoing flood and natural hazard management, including costs associated with the operation and maintenance of flood and erosion control infrastructure by 20 to 80% depending on differences in urban density and property values.

These policies have been credited with keeping losses associated with flooding in Ontario lower than losses seen in other Canadian provinces. Responsibility for keeping development out of floodplains is a shared responsibility between municipalities (enforced through municipal planning) and conservation authorities (enforced through regulations made under Section 28 of the *Conservation Authorities Act*).

These policies will be increasingly valuable in protecting Ontarians from flooding and other natural hazards. Losses associated with flooding and other natural hazards continue to increase because of increasing property values and income levels, urbanization, ongoing loss of wetlands and other green infrastructure, and the increasing frequency and intensity of extreme rainfall events. As these losses rise, so does the value of Ontario's floodplain and broader hazard management policies.

5.2.1 The Planning Act and the Provincial Policy Statement

The *Planning Act* and the Provincial Policy Statement (PPS) are the primary provincial tools used to guide local land use planning decisions made by municipalities in Ontario. The PPS is the primary provincial land use policy document guiding municipal decision-making. The *Planning Act* requires that decisions on land use planning matters be “consistent with” the PPS, and the PPS policies provide the foundation for regulating development.

Municipalities are the primary implementers of the PPS through incorporation of policies into their local official plans, zoning by-laws and other planning-related decisions.

The PPS is administered by the Ministry of Municipal Affairs and Housing (MMAH), and provides policy direction on matters of provincial interest related to land use planning and development, sets the policy foundation for regulating the development and use of land, and supports the provincial goal of enhancing the quality of life of all Ontarians. The focus of the PPS is on guiding municipal decision making regarding new development and redevelopment.

While this Act and Policy is led by MMAH, the MNRF has the lead in developing the natural hazard policies, including policy direction related to flooding/flood hazards, in Section 3.0 of the PPS. The MNRF works with partners and experts in the development of these policies, which are reviewed every 10 years. These policies require municipalities to identify areas subject to natural hazards in order to consider public safety when planning for new development. To support implementation of policies in the PPS, subject area specific guidance is developed by ministries having the lead for those specific policies in collaboration with other applicable ministries. A series of natural hazard technical guides have been developed by the MNRF to support

implementation of Section 3.0 of the PPS, and are further outlined in Section 5.2.6 below.

The Ministry of Municipal Affairs and Housing conducted consultations from July 22 to October 21, 2019, on proposed changes to the Provincial Policy Statement (PPS) to help increase the supply of housing, support jobs and reduce barriers and costs in the land use planning system (see the Ontario Government website at <https://ero.ontario.ca/notice/019-0279> and titled: “Provincial Policy Statement Review – Proposed Policies”). Specifically related to flooding, the proposed policies would enhance direction to prepare for impacts of a changing climate; enhance stormwater management policies to protect water and support climate resiliency; and maintain current policies related to natural and human-made hazards, which directs development away from hazardous areas including flood-prone areas in order to protect public health and safety. Given the direct correlation between the policies in Section 3.0 of the PPS and the Special Advisor on Flooding review, a placeholder was put on these policies in the draft PPS being consulted, until the government has an opportunity to consider the recommendations made in relation to potential policy changes.

5.2.2 The Conservation Authorities Act

The purpose of the *Conservation Authorities Act* is to provide for the organization and delivery of programs and services that further the conservation, restoration, development and management of natural resources in watersheds in Ontario through the establishment of conservation authorities (CAs) organized on a watershed scale. A CA is a municipal public sector organization whose governing structure of members (similar to a Board of Directors) are appointed representatives from the municipalities that established or may have joined the CA and who mostly fund the CA. Many members, for reasons of fiscal accountability, are elected municipal officials. A CA provides programs and services in local resource management within its jurisdiction to both the Province and municipalities.

In 1956, in response to severe economic and human losses associated with Hurricane Hazel (1954), amendments to the *Conservation Authorities Act* empowered CAs to make regulations to prohibit filling in floodplains. These regulations were broadened in 1960 to prohibit or regulate the placing or dumping of fill in defined areas where, in the opinion of the CA, the control of flooding, pollution or the conservation of land may be affected. In 1968, amendments to the *Conservation Authorities Act* further extended the regulations to prohibit or control construction and alteration to waterways. In 1983, the Minister of Natural Resources delegated to CAs the commenting responsibilities for floodplain management matters. CAs would have the authority to review planning

documents and provide comments to federal, provincial ministries and agencies, municipalities and private landowners, including developers.

In 1988, the Minister delegated commenting responsibilities to CAs for matters related to flooding, erosion and dynamic beaches along the shoreline of the Great Lakes/St. Lawrence River System.

In 1995, the Minister confirmed CAs as lead commenting agencies for riverine erosion, slope and soil instability matters, such as areas of high water tables, organic or peat soils, and Leda or sensitive (unstable) marine clay soils.

The regulatory scope of CAs was broadened again in 1998, giving them the authority to regulate development activities adjacent to Great Lakes shorelines, interconnecting channels and inland lakes, and the authority to regulate activities that may interfere with the hydrologic function of wetlands.

With the advent of the provincial One Window Planning Service, an agreement was developed in 2001 with the MNRF, MMAH and Conservation Ontario to define the roles and relationships between CAs, the MNRF and MMAH in planning for implementation of CA delegated responsibilities under this system. The Agreement focuses on MNRF delegated responsibilities to CAs for the PPS Section 3.1 – Natural Hazard Policies. The CA delegated role does not extend to other portions of the PPS unless specifically delegated in writing by the Province. CAs, as public bodies under the *Planning Act*, can comment on official plans or development applications on other portions of the PPS but not with the same authority as the delegated commenting role.

Each of Ontario's 36 conservation authorities currently administer an individual conservation authority "Development and Interference" regulation approved by the Minister of Natural Resources and Forestry, conforming to the requirements prescribed under Ontario Regulation 97/04 – Content of Conservation Authority Regulations Under Section 28 (1) of the Act: Development, Interference with Wetlands and Alterations to Shorelines and Watercourses. A key provincial responsibility that CAs have within their jurisdiction is the regulatory authority under Section 28 of the *Conservation Authorities Act*—the regulating of development and activities through the permitting process in hazard-prone areas set out in regulation for purposes of public safety and natural hazard management. These regulations are a critical component of Ontario's broader natural hazard management framework and are designed to achieve the following policy objectives:

- Preventing loss of life, minimizing property damage and social disruption;

- Reducing public and private expenditure for emergency operation, evacuation, restoration and protection measures;
- Regulating development which, singularly or collectively, impact upon existing flood levels, and increasing potential risks to upstream and downstream landowners;
- Control interference with natural storage areas such as wetlands;
- Conserving land through the control of development on existing or potentially unstable valley slopes or shoreline bluffs; and
- Controlling development impacts as they relate to pollution (including erosion & sedimentation) or other degradation of existing and water resources, including groundwater.

Section (4) of the regulation requires that CAs geographically describe the hazardous lands and areas susceptible to flooding based on the design flood event that is applicable (i.e. Hurricane Hazel, the Timmins event, the 100 year, etc.), and details of rain intensity, duration and impacted area are included in an appendix. This geographical description of the regulatory limits can include reference to maps filed at the head office and the regulations specific to each CA identifies that, where there is a conflict in the description of areas identified in maps, the text description of the regulated areas prevails. Floodplain and other hazard mapping and related studies provide a support for implementing the conservation authority regulations under the *Conservation Authorities Act* and for the conservation authority commenting role on official plan review activities delegated under the *Planning Act*.

Conservation authority activities are funded through a combination of shared provincial and municipal funding, municipal levy and self-financing. Floodplain mapping and technical studies for delineation of hazard areas for municipal planning (not the authority regulations) are among the items eligible for the cost-shared provincial and municipal funding.

The MNRF continues as lead administrative ministry having overall government responsibility for natural hazard management policies/programs.

The MNRF has proposed changes to regulations administered by CAs and the public was consulted between April 5 and May 21, 2019. The following excerpts are from the Ontario Government's website titled: "Focusing conservation authority development permits on the protection of people and property" (refer to <https://ero.ontario.ca/notice/013-4992>).

The MNRF is proposing a regulation that outlines how conservation authorities permit development and other activities for impacts to the control of natural hazards and public safety. The proposed regulation will make rules for development in hazardous areas more consistent to support faster, more predictable and less costly approvals.

Prohibited activities set out in the un-proclaimed provisions of Section 28 of the *Conservation Authorities Act* as amended by Schedule 4 of the *Building Better Communities and Conserving Watersheds Act, 2017* include:

- Development in areas related to natural hazards such as floodplains, shorelines, wetlands and hazardous lands (i.e. lands that could be unsafe for development because of naturally occurring processes associated with flooding, erosion, dynamic beaches or unstable soil or bedrock); and
- Interference with or alterations to a watercourse or wetland.

The Ministry is proposing to create a regulation further defining the ability of a conservation authority to regulate prohibited development and other activities for impacts to natural hazards, including flooding and to public safety.

The Ministry is proposing to consolidate and harmonize the existing 36 individual conservation authority-approved regulations into one Minister of Natural Resources and Forestry approved regulation to help ensure consistency in requirements across all conservation authorities while still allowing for local flexibility based on differences in risks posed by flooding and other natural hazards.

Of note, the Ministry is also proposing under this regulation to:

- Allow conservation authorities to exempt low-risk development activities from requiring a permit provided in accordance with conservation authority policies;
- Require conservation authorities to develop, consult on, make publicly available and periodically review internal policies that guide permitting decisions; and
- Require conservation authorities to notify the public of changes to mapped regulated areas such as floodplains or wetland boundaries.

Ensuring conservation authority permitting decisions focus and deliver on their core mandate of protecting people and property from flooding and other natural hazards is part of the government's Made-in-Ontario Environment Plan to help communities and families prepare and respond to climate change. The proposed changes will also provide the business sector with a clear and consistent

regulatory environment in which to operate and will help to make approval processes faster, more predictable and less costly.

As more extreme weather events occur that threaten homes, businesses and infrastructure, it's important to ensure conservation authorities deliver on their core mandate for protecting people and property from flooding and other natural hazards. Improving the efficiency and effectiveness of these regulations is a critical component of this government's strategy for strengthening Ontario's resiliency to extreme weather events.

The MNRF believe this regulation is a critical component of Ontario's approach to reducing risks posed by flooding and other natural hazards and strengthening Ontario's resiliency to extreme weather events.

At the same time as the MNRF public review period for proposed changes to regulations, the Ministry of the Environment, Conservation and Parks consulted with the public on proposed amendments to the *Conservation Authorities Act*, which, if passed, would help conservation authorities focus and deliver on their core mandate, and improve governance. More information can be found on the Ontario Government's website titled: "Modernizing conservation authority operations - Conservation Authorities Act" (refer to <https://ero.ontario.ca/notice/013-5018>).

One of the stated areas of focus for conservation authorities will be providing programs and services related to managing risks posed by natural hazards, including flooding. The specific programs and services to be provided by conservation authorities related to flooding and other natural hazards are set to be outlined in regulation.

5.2.3 Lakes and Rivers Improvement Act and Water Management Planning

The *Lakes and Rivers Improvement Act* (LRIA) provides the Minister of Natural Resources and Forestry with the legislative authority to govern the design, construction, operation, maintenance and safety of dams in Ontario. The *Lakes and Rivers Improvement Act* and Ontario Regulation 454/96 require dam owners to obtain approval from the MNRF for the construction of new dams, certain repairs and alterations to existing dams, and certain water crossings and channelization works.

The *Lakes and Rivers Improvement Act* Administrative Guide and supporting technical bulletins and best management practices have been prepared to provide direction to MNRF staff responsible for application review and approval, and guidance to applicants who are seeking approval under the LRIA.

Normal operating ranges for dams authorized under the LRIA are described in Water Management Plans or site-specific operating plans for dams located outside the geographical boundary of a water management plan.

The LRIA was amended in 2002 to create a regulatory framework for existing dam operations. The amendments established the statutory authority for the Minister of Natural Resources and Forestry to order an owner of an existing dam to prepare or amend a management plan for the operation and maintenance of the dam, consistent with Minister approved guidelines.

To implement this legislative amendment, the Water Management Planning Guidelines for Waterpower 2002 (WMPG) were approved by the Minister of Natural Resources and Forestry. The goal of water management planning was to contribute to the environmental, social and economic well-being of the people of Ontario through the sustainable development of waterpower resources, by managing these resources in an ecologically sustainable way. The WMPGs established a planning process for defining goals, objectives, scope and criteria for the preparation of Water Management Plans (WMP). WMPs are owned by the primary waterpower producer and must be prepared with the input of stakeholders along the river to which it is situated.

Existing waterpower facilities on rivers in provincial jurisdiction were ordered to prepare plans for the management of flows and levels at their generating stations. In some instances, owners of non-power producing water control structures within the same river were required to participate in water management planning for rivers in which their dams were situated, if their dams were integral to the regulation of flows and levels.

“Complex” WMPs were generally prepared for rivers with multiple waterpower facilities or control structures with significant control over water levels and flows. Complex plans typically had more than one plan proponent (dam owner or waterpower facility owner) and/or significant competing interests.

“Simplified” WMPs were prepared for sections of rivers where there were one or more waterpower facilities or water control structures that generally had limited control of water levels and flows.

WMPs describe the normal range of operating conditions, defined in terms of seasonal flows and levels for each dam within a WMP. The provisions of a WMP do not apply in the event of a declared flood, low water condition or emergency situation.

In 2016, the Ministry approved the Maintaining Water Management Plans Technical Bulletin, which replaces the 2002 Water Management Planning Guidelines and its appendices.

5.3 Organizational Roles and Responsibilities

In Canada, flood management is the responsibility of the provinces and territories, and is often delegated to municipalities through legislation. Therefore, most flood management activities including mapping, planning, preparation, response and recovery are executed at the local rather than provincial, territorial or federal levels. The management of flooding hazards, including the prevention and mitigation of impacts, is a coordinated approach by the province, municipalities and conservation authorities. The federal government can become involved if federal disaster assistance is triggered. Management is achieved through a series of provincial acts, regulations, policies, and technical guides (see Section 5.2), which together enable local decision making to protect people and property from the impacts of flooding. These individual tools are managed by various agencies in the province based on expertise, creating a network of policies which together implement the flood management program.

5.3.1 Ministry of Natural Resources and Forestry

Since 1975 and re-affirmed by Order-in-Council 1157/2009 of the *Emergency Management and Civil Protection Act*, the MNRF is the provincial lead for seven hazards, including floods.

While the MNRF plays a major role in flood response and response support, the MNRF's current approach focuses on prevention—keeping people out of harm's way and minimizing loss of human life, injury, damage to property and the environment, and mitigation of economic and social disruption through a range of legislative, policy and technical mechanisms. As part of this approach, regulatory and land use restrictions are developed by the MNRF and put in place by municipalities through the Provincial Policy Statement (PPS) land use planning policies, with their implementation supported by a series of technical guidelines produced by the MNRF. Also, under the *Planning Act*, conservation authorities have a delegated responsibility through the MNRF to provide plan input on matters of provincial interest relating to Section 3.1 of the PPS focusing on the Official Plan and Official Plan Amendment stages as well as site plan applications, on a site-by-site basis. In combination, these actions work to prevent new or intensified development in areas prone to flooding and other natural hazards, and regulate activities that can create or increase hazards (e.g. alterations to watercourses and wetlands). The MNRF does not have its own piece of legislation to implement the hazard program and uses a series of tools to enable flood management. These program tools include:

- The *Planning Act* and Provincial Policy Statement (see Section 5.2.1 above);
- The *Conservation Authorities Act* (see Section 5.2.2 above);

- Natural Hazard Technical Guides (see Section 5.2.6 above);
- Mapping and Geomatics Services (see Section 5.3.1.1 below); and
- Flood Forecasting and Warning Services (see Section 5.3.1.2 below).

5.3.1.1 Mapping and Geomatics Services

Geospatial data is critical to flood mapping as it serves as authoritative data for the entire flood mapping process. The two main types of geospatial datasets used in flood mapping are: 1) Imagery, for two-dimensional feature positions (e.g. roads, rivers and buildings); and 2) Elevation, for three dimensional heights (e.g. height of riverbank, height of road).

The Mapping and Geomatics Services Section (MGSS) of the Mapping and Information Resources Branch in the MNRF is responsible for capturing, creating and maintaining Ontario’s foundation geospatial data/base data for government, academia and the general public.

The MGSS acquires, maintains and distributes authoritative, open, provincial-scale geospatial data by coordinating provincial acquisition projects (imagery, elevation, LiDAR, bathymetry, roads, water, wetlands, etc.); developing mapping guidelines and standards; providing leadership and guidance in the management of geospatial data; establishing data sharing agreements and funding partnerships between local, provincial and national agencies; and making data discoverable and accessible as Open Data.

Besides its responsibilities for provincial-scale mapping and MNRF geomatics, the MGSS also coordinates the Land Information Ontario program (LIO) on behalf of all Ontario ministries. LIO improves geospatial service delivery for Ontario Public Service (OPS) ministries and partners by:

- Coordinating governance for collective decision making and leadership;
- Engaging with geospatial communities to identify needs;
- Delivering services and products that meet common needs and realize collective benefits; and
- Sharing geospatial knowledge to establish and review best practices.

LIO’s core principles include the value of collaboration for geospatial data and services and the principle of “do once, use many times.” A good example of this is the LIO Imagery Program, which acquires high-resolution imagery for the provincial government

and numerous partners across the private, public and academic sectors. The success of the LIO Imagery Program is defined by:

- Leveraging internal and external partnerships across multiple sectors;
- Meeting multiple business needs;
- Achieving financial cost sharing; and
- Establishing a predictable, 5-year imagery acquisition cycle.

5.3.1.2 Flood Forecasting and Warning Services

Flood forecasting and warning services are delivered by the MNRF through its Surface Water Monitoring Centre (SWMC) in cooperation with conservation authorities where they have been established and local MNRF district offices, which provide local level expertise and information through flood warning and watch messages to municipal responders.

The ability to provide this service rests with information provided through the hydrometric network, a federal/provincial partnership, and its 600 gauges across the province, more heavily concentrated in those watersheds of greatest population and therefore greatest risk of harm.

The agreement requires a monetary investment by the Province, most recently in the amount of \$4.6M for 2019/20. It is expected that the cost of the agreement will increase at an annual inflationary rate of 2% per year. The agreement ensures that the gauges are monitored and maintained to provide the “eyes on the ground” toward flood forecasting.

While there are a number of recommendations in Section 6.3 to improve preparedness, the SWMC advises that it is committed to and continues to learn from each event, and has undertaken numerous steps toward continuous improvement. These actions include:

- Implemented a new Kisters WISKI data environment and developed multiple new products for scripting custom products to improve operations.
- Developed a new early warning system for static (calm) water levels on the Great Lakes and consolidated working relationships with federal government for Great Lakes Briefing products.
- Developed new tools for communicating Ottawa River Secretariat forecasts to conservation authorities and district offices of the Ministry of Natural Resources and Forestry.

- Initiated updates to provincial flood forecasting and warning guidelines (scheduled for completion in 2020).
- Sponsored transfer payment funding to multiple conservation authorities for new flood communication tools on the Ottawa River, GAWSER snowmelt modelling routine in WISKI, and HEC-HMS model development. The Province can evaluate and use these products now that they have been developed.
- Sponsored multiple knowledge transfer and training sessions for internal and external clients—After Action reviews, modelling and technology transfer, flood forecasting and warning community workshops, annual internal training, and collaboration with hydrometric network partners.
- Restructured business practices with Water Surveys Canada to improve field responses to gauge maintenance and field measurements for record events.
- Implementing a new communications plan, including webpage refreshes and web usage statistics.

5.3.1.3 Remote Sensing Science Group

The hub of remote sensing expertise in the provincial government is housed within the MNRF's Provincial Services Division (PSD), Science and Research Branch (SRB), Forest Resource Inventory (FRI) Unit. The Remote Sensing Science Group is primarily focused on Provincial Land Cover and Disturbance mapping and, as provincial data custodians, they support a wide range of users and applications. They also possess the skills and experience necessary to support Emergency Management Near Real Time image processing, interpretation, automation and publishing. Operationally, to support provincial emergency management flooding efforts, the Remote Sensing Science Group works closely with the Surface Water Monitoring Centre and Natural Resources Canada's (NRCan) Canada Centre for Remote Sensing and Emergency Geomatics Services Offices.

Two remote sensing products are primarily used by the group—the Canadian Space Agency's RADARSAT-2 and NASA's MODIS. These products provide more spatial information on water, ice and watershed conditions, information between stream gauges, information in remote areas, quantify conditions that cannot be determined from stream gauges, and are used to assess risk, inform flood messaging and emergency operations. They add to the body of knowledge available about flood, ice and more, and supplement human efforts on the ground (i.e. reconnaissance flights, snow surveys, ice observations). In short, these products help to make better, more informed decisions about a flood.

RADARSAT imagery allows for the accurate mapping of ice conditions through inclement weather and night time hours (as opposed to major limitations with optical imagery and local reconnaissance flights). With frequent revisit times, RADARSAT images can be acquired several times per week for each river, which improves the ability for the early detection of ice jamming.

RADARSAT is also used to provide near real time flood maps and information (extent, severity and progression); greatly improves situational awareness during flood events; facilitates better decision making and flood forecasting; creates documentation and increases knowledge that supports future flood management; and supports the development of accurate floodplain maps.

MODIS Optical Imagery is used to monitor river ice breakup in Ontario's far north coastal rivers. Acquisition, interpretation and communication used to be an entirely manual process; however, in-house tool enhancements from 2016 to 2019 have resulted in an entirely automated process.

The Canadian Space Agency is replacing the RADARSAT-2 satellite with three small identical satellites under the RADARSAT Constellation Mission (RCM), which were launched on June 12, 2019. The RCM will capture images of the earth's water, land, ice and atmosphere during the day and night and in all types of weather, including heavy cloud cover, smoke and haze, which is a huge improvement in optical products. The new RADARSAT Constellation will provide near real time data for all of Ontario and provide more information to support the assessment of flood risk, effective flood messaging and emergency operations.

5.3.2 Ministry of Municipal Affairs and Housing

The Ministry of Municipal Affairs and Housing (MMAH), in their role as lead agency for the administration of the *Planning Act* and the Provincial Policy Statement (PPS), plays a critical role in supporting the MNRF through inclusion of hazard policies in the PPS for new development and redevelopment, as previously discussed in Section 5.2.1 above.

MMAH also delivers the Disaster Recovery Assistance for Ontarians (DRAO) program (for private property owners) and at the municipal level, the Municipal Disaster Recovery Assistance (MDRA) program for eligible expenses following a natural disaster (see Section 5.1.5 above).

In addition to these programs, and in response to flooding in the spring of 2019, MMAH created a \$1 million pilot project designed to help municipalities repair flood damaged roads, bridges and other infrastructure to a higher standard, meaning they can better withstand extreme weather. As part of a \$1 million pilot project, the Province will

provide municipalities that qualify for MDRA funding with up to 15% above the estimated cost of rebuilding damaged public infrastructure to make it more resilient to extreme weather. Examples include raising roads to provide better protection from overland flow of water, improving the columns or footings of bridges, or increasing the size of ditches and catch basins to increase their capacity to hold water. Communities that were affected by spring flooding that occurred after March 1, 2019, are eligible for the enhanced funding under the pilot.

5.3.3 Ministry of Environment, Conservation and Parks

The Ministry of Environment, Conservation and Parks (MECP), with priority on protection of public safety and the environment, is the provincial lead for a number of water-related initiatives including:

- Protecting the Great Lakes;
- Protecting waterways and inland waters;
- Ensuring sustainable water use and water security for future generations;
- Providing provincial oversight of municipal and private wastewater and stormwater; and
- Enhancing data, information and knowledge sharing.

MECP also has overall responsibility for the *Conservation Authorities Act* and non-natural hazard related programs and services developed and delivered by CAs.

Ontario's 2018 Environment Plan outlines the government's intention to undertake a comprehensive, multi-sectoral assessment of climate change-related impacts, including vulnerabilities, risks and opportunities, to help provide a detailed understanding of how and where climate change will affect Ontario's economy, infrastructure, communities, public health and safety and ecosystems, and what the likely challenges and opportunities associated with those impacts would be. The draft plan commits to working with industry, such as real estate and insurance, to raise awareness among homeowners about the increasing risk of flooding as more frequent extreme weather events are being experienced. This initiative is also being led by MECP.

MECP develops municipal guidance documents to support stormwater management planning and design, which assists municipalities in developing stormwater servicing master plans as well as planning for infrastructure that provide protection of public safety and the environment.

5.3.4 Ministry of Infrastructure

The Ministry of Infrastructure's connection to flood management and prevention is:

- MOI is responsible for making recommendations on priorities for infrastructure and effective coordination of infrastructure across provincial ministries within the government.
- MOI works with partner ministries and Infrastructure Ontario to design, implement and administer public infrastructure programs.
- MOI manages the Asset Management Planning for Municipal Infrastructure Regulation, O. Reg. 588/17, which guides asset management and provides tools and support for municipalities in Ontario to meet their current and future infrastructure needs (see <https://www.ontario.ca/page/municipal-asset-management-planning>).
- MOI leads the design and implementation of federal-provincial infrastructure programs, working with partner ministries and the federal government.

Resilient infrastructure that helps communities cope with the intensifying effects of climate change and floods has become a key area for targeted investment for MOI in recent years.

MOI administers the Ontario Community Infrastructure Fund (OCIF) which, since 2014, has provided application- and predictable formula-based funding to help build and repair core infrastructure (e.g. road, bridge, water, wastewater infrastructure) in more than 420 small, rural and northern communities. The Province is currently reviewing the design of the OCIF to ensure that it continues to support municipalities to improve and implement asset management plans.

The Green stream of the Investing in Canada Infrastructure Program (ICIP) consists of up to \$7.12 billion in combined federal (\$2.85 billion), provincial (\$2.3 billion), and other partner (\$1.92 billion) funding for projects that improve outcomes under one of the three federal sub-streams—Climate Change Mitigation, Environmental Quality, and Disaster Mitigation.

MOI launched the first intake of the Green stream on October 25, 2019 (see <https://news.ontario.ca/moi/en/2019/10/ontario-investing-in-green-infrastructure-to-help-smaller-communities.html>). The focus of this first intake is to address critical health and safety issues in small municipalities and First Nations communities with populations under 100,000 for water, wastewater and stormwater infrastructure.

MOI will be working with other government departments, including the MNRF, to design additional intakes of the Green stream that could support innovative natural infrastructure and green technology solutions to address current and future challenges in environmental quality, climate change and disaster mitigation.

5.3.5 Office of the Fire Marshall and Emergency Management (Ministry of the Solicitor General)

The Office of the Fire Marshall and Emergency Management, Emergency Management Branch—better known as Emergency Management Ontario (EMO)—is the overall provincial emergency management organization and is responsible for monitoring, coordinating and assisting in the development and implementation of effective emergency management programs throughout Ontario, and for the coordination of these programs with the federal government. In fulfilling this special coordination role, EMO coordinates the provincial emergency response through the Provincial Emergency Operations Centre, when required; provides advice and assistance to communities and ministries in all areas of emergency management; and maintains two provincial level emergency response plans—the Provincial Nuclear Emergency Response Plan and the Provincial Emergency Response Plan (PERP).

The PERP is the plan that is used to coordinate overall provincial emergency response and outlines how EMO and the ministries respond to widespread or large-scale emergencies.

Key initiatives of EMO related to flooding include hosting an annual flood and forest fire symposium, publishing and holding workshops on Hazard Identification and Risk Assessment; conducting a review of national and international best practices to evolve the program; updating the Provincial Emergency Response Plan; and updating the Incident Management System.

For flood events, the Provincial Emergency Operations Centre (PEOC) outreaches to Community Emergency Management Coordinators potentially impacted by flooding to determine anticipated resource requests; develops GIS mapping and incident information products for situational awareness; deploys field officers to provide advice to municipalities and liaise between the PEOC and on-site responders; and develops and circulates flood resource materials (lists of flood-related resources and materials and a Flood Recovery Guide).

5.3.6 Municipalities

In the MNRF technical guides, municipalities are delegated the responsibility under the *Emergency Management and Civil Protection Act* of identifying areas subject to natural

hazards and to develop management plans (i.e. flood contingency plans) to limit exposure to public health and safety risks. This includes identifying floodplains in municipal plans and incorporating policies to address new development consistent with the PPS policy. It is up to the municipality to determine how best to achieve this requirement and the use of floodplain mapping is one tool available to demonstrate hazard areas. Municipalities can choose to involve their conservation authority in preparing floodplain mapping on the municipality's behalf, but are not required to do so.

Any updated or new mapping is generally funded on an as-needed priority basis by municipalities, or through proponent driven development applications. Neither the MNRF nor the Province provides funding for new or updated flood hazard mapping, nor approves new or updated mapping; however, the Province has provided small transfer payments for pilot projects related to mapping technologies in the last few years.

Maps are retained at the municipality and are used for specific land use planning purposes. It is up to the municipality to update their maps when required, which usually is development driven, including updates or amendments to official plans. The MNRF does not track or monitor the development of mapping locally and cannot report on its status or progress.

Municipalities are responsible for municipal stormwater management (e.g. planning, standards, design, establishment, operation and maintenance). Municipal stormwater management deals with the component of the urban surface runoff that is or would be collected by means of separate municipal storm sewers and, in some areas, by combined sewers.

Municipal stormwater management can include green infrastructure that captures (partially or fully) where snow melts or rain falls, reducing stormwater runoff that enters municipal storm sewers.

Municipalities also have an important role for managing surface runoff in rural areas. They, along with landowners, have responsibility for municipal drains that drain and convey surface runoff under the *Drainage Act*. Tile drains, which are important to agricultural productivity, collect and convey surface runoff to natural waterways directly or indirectly via municipal drains. Surface runoff from municipal roads are also conveyed and release to natural waterways. The cumulative drainage of the vast rural areas and rapid conveyance contributes to downstream urban (fluvial) flooding risk.

In emergencies, municipalities undertake first response activities and are responsible for recovery efforts in their jurisdiction.

5.3.7 Conservation Authorities

Conservation authorities are public sector bodies established by municipalities through the *Conservation Authorities Act* (see Section 5.2.2. above) that deliver programs and services, and regulate development and activities set out in regulations within their jurisdiction through a permitting process if the development may impact the control of natural hazards, including riverine and shoreline flooding, or if activities interfere with a watercourse or wetland. Conservation authorities also have a delegated role from the MNRF in reviewing municipal planning documents and applications under the *Planning Act* for consistency with the natural hazard policies in the PPS, including how the development may impact the control of natural hazards. These responsibilities include policy interpretation and the transfer of data, information and science to municipalities. The delineation of hazard areas through mapping and supporting hydrologic/hydraulic studies provides important information and science to support these delegated responsibilities. Regulatory mapping may be updated by a conservation authority from time to time, sometimes when municipalities update their official plans and their floodplain mapping or, as a requirement of a permit application, a proponent may be required to update authority regulatory mapping.

Where they have been established, conservation authorities are delegated with the responsibility for flood forecasting and warning. Where no CA exists, the local MNRF district is responsible. Supporting both CAs and MNRF districts is the MNRF's Surface Water Monitoring Centre, whose main function is to monitor water flows and levels, assess conditions across the province, and provide communications and ongoing knowledge of the provincial flood potential. The scope and complexity of a flood forecasting and warning program for a particular jurisdiction is contingent on a variety of considerations, including the level of risk within flood-prone areas. Some conservation authorities may operate and maintain an additional network of streamflow, snowpack, rain gauges and climate stations throughout their geographical jurisdictions that can also serve as data inputs to their hydrologic models to address the specific needs within their jurisdiction.

5.3.8 The Federal Government

Water management and flood hazard management more specifically are not referenced in the Canadian *Constitution Act*. Provincial water management authority is derived from the authority to legislate over property and civil rights, over matters of local and private nature, over local works and over natural resources. Some federal departments such as Natural Resources Canada (NRCan) also have a role in flooding and other natural hazards. NRCan monitors natural hazards (including flooding and landslides) and provides information about hazards events, as well as information to help

Canadians understand and prepare for natural hazards, and to reduce the losses from hazards events. NRCan develops and distributes geospatial data, topographic and geoscience maps, images and scientific publications associated with flooding and landslides. (See also the discussion on remote sensing in Section 5.3.1.3.)

Public Safety Canada administers the Disaster Financial Assistance Arrangements (DFAA) program, which reimburses provincial and territorial governments for eligible disaster response and recovery costs.

With flooding being the single largest draw on DFAA, NRCan initiated the Federal Flood Mapping Guidelines Series (in partnership with Public Safety Canada) to provide critical support to areas in Canada that didn't necessarily have robust guidance related to floodplain mapping. While well intentioned, this initiative has added to confusion in Ontario, with practitioners not necessarily understanding that Ontario's existing guides take precedence.

Public Safety Canada also provides funding for cost-shared projects related to the management of flooding and other natural hazards through programs like the National Disaster Mitigation Program (NDMP) and Infrastructure Canada provides funding through the Disaster Mitigation and Adaptation Fund (DMAF). Flood-related infrastructure projects may also be eligible for funding under the Investing in Canada Infrastructure Program (ICIP) under the Green stream administered jointly by Infrastructure Canada and Ontario.

5.3.9 Other Agencies

5.3.9.1 International Joint Commission

Canada and the United States are parties to the Boundary Waters Treaty of 1909 (the Treaty), under which the International Joint Commission (IJC) is created. Under the Treaty, IJC has the jurisdiction over cases involving the use, obstruction or diversion of boundary waters shared between Canada and the U.S. For instance, the regulation of water flow through the Moses-Saunders Dam on the St. Lawrence River fall under the jurisdiction of the IJC.

Ontario works closely with the IJC and federal, state and provincial governments to ensure Great Lakes regulation strategies account for sustainable water resources management. While Ontario is not responsible for managing outflows from the Great Lakes, the Province does have responsibilities for lands, tourism, land use planning, water use and natural hazard management (erosion, flooding), all of which are affected by water levels and flows.

The MNRF advises the International Joint Commission through IJC Boards of Control and short-term task forces and studies.

5.3.9.2 Ottawa River Regulation Planning Board

In 1983, Canada, Quebec and Ontario approved the Agreement Respecting Ottawa River Basin Regulation. Under its terms, a board was constituted to plan and recommend regulation policies and criteria leading to integrated management of the 13 principal reservoirs of the basin, taking into account flood protection, hydroelectric power production and other interests. Supported by a Regulating Committee composed of the four agencies that own and operate the reservoirs and Secretariat, the Ottawa River Regulation Planning Board endeavours to ensure that the integrated management of the reservoirs provides as much protection as possible (the generating stations on the main stem of the Ottawa River were not designed for flood protection) against flooding along the Ottawa River and its tributaries, and along its channels in the Montréal region. The term "integrated management" means that the four principal dam operators in the basin operate their facilities with knowledge of what the other operators are doing and the consequences of operational decisions elsewhere in the Ottawa River basin.

The Board consists of seven members, each with an alternate, who represent Canada (three members), Ontario (two members), and Quebec (two members). The two Ontario agencies represented include the MNRF (co-chair of the board) and Ontario Power Generation (OPG).

On the Ottawa River, the responsibility and authority to manage dams in accordance with established operating plans rest with dam owners (e.g. Hydro-Québec, Ontario Power Generation and the federal government through Public Services and Procurement Canada). The Ministry's application of the *Lakes and Rivers Improvement Act* on existing Ottawa River facilities is limited to reviews and approval of repairs/upgrades per associated work permits.

5.3.9.3 Ontario Power Generation

Ontario Power Generation (OPG) has been a member of the Ottawa River Regulation Planning Board (ORRPB) since its inception and is a full member of the Ottawa River Regulating Committee (ORRC) of the ORRPB. As part of the Regulating Committee, OPG collaborates with other operators of principal reservoirs to optimize the use of the storage they manage in view of reducing the river flows downstream, thereby minimizing flooding. In the spring, OPG and other operators follow river condition forecasts provided through the Regulating Committee very closely in order to make appropriate decisions at their facilities.

As agreed by Canada, Ontario and Quebec, the Board is the administrative and policy branch of the organization and the Regulating Committee and Secretariat are the operational arms. The purpose of the ORRPB and ORRC is to ensure integrated management, or the collaborative management, of the 13 principal reservoirs of the Ottawa River to minimize the impact of flooding and droughts along the Ottawa River. The original language in the ORPPB/ORRC agreement from the early 1980s states that the goal of the integrated management is to “provide protection against flooding.” The term “protection” is a misnomer, as the location of existing reservoirs and their physical storage capacity does not provide the ability to fully protect against flooding. Integrated management on the Ottawa River does not prevent the impact of flooding, but reduces the impact of flooding to the greatest extent possible given physical constraints.

Integrated management does not mean that the ORRPB or ORRC dictate or control flows in the river. Instead, the ORRPB mandate is to ensure that all operators are sharing information and forecasts when making decisions and that all decisions are made with the full knowledge of what other operators are doing. Being involved in the management of the principal reservoirs in the Ottawa River basin, OPG communicates and exchanges information at least daily with other members of the Regulating Committee (Hydro-Québec, Québec and Canada) throughout the spring flood season to assess together current and forecast river conditions, and what actions may be required to minimize flood impacts.

The daily process starts with the ORRC members examining the current water level and flow conditions at their facilities and submitting hydrometric data and initial reservoir release decisions. Hydro-Quebec produces a hydrological forecast of inflows along the river, which is shared with the Secretariat and ORRC members. This information is used as input to the reservoir routing model for forecasting flows and levels throughout the river system to aid ORRC members in planning operations (i.e. storage/discharge decisions). Members of the ORRC review the results and discuss the current operational strategy on a conference call. If at this time OPG decides it best to modify their reservoir operation strategy, they will inform the ORRC and the reservoir routing model will be modified to examine the impact of the change in this decision. This process will occur until a final strategy is established. At all times, OPG is responsible for the operation and strategy relating to its facilities. The ORRPB/ORRS/ORRC structure ensures that the operators’ decisions are transparent, consistent and share a common understanding of the watershed conditions with other members.

Chapter 6

Challenges and Opportunities to Managing Flood Risk

Although Ontario has a well-established approach to managing flood risk, the reality is that there have been significant property and casualty losses associated with extreme weather events in the past several years. According to Canada's Parliamentary Budget Officer, the estimated annual DFAA costs resulting from floods are the largest of the weather events (others being hurricanes, convective storms and winter storms) representing 75% of all weather-related expenditures (refer to https://www.pbo-dpb.gc.ca/web/default/files/Documents/Reports/2016/DFAA/DFAA_EN.pdf).

The public should understand that the risk of flooding cannot be eliminated, but it can be reduced. There are considerable challenges to managing flooding especially when governments are having fiscal challenges. However, there are many opportunities to improve on the current approaches to managing flood risk.

6.1 Prevention

6.1.1 Gaps in Policy and Technical Guidance

Components of the current technical guides and associated standards are outdated and need to be updated to reflect emerging environmental concerns and new land use policies.

Beginning in 2016, the MNRF initiated work to better understand and start to address current gaps in policy, and document issues and concerns with technical guidance, including many of the components highlighted in sections below. In some circumstances, specific conservation authorities have developed and adopted their own policies and technical guides which may not be consistent with MNRF's guidance or the Provincial Policy Statement (PPS).

This section is included specifically to highlight the gaps in policy and technical guidance. Subsequent sections get into more detail and result in specific recommendations.

6.1.1.1 Lack of Guidance for Considering Climate Change

Changes made to the PPS in 2014 direct municipalities to consider the potential impacts of climate change that may increase the risk associated with flooding and other natural hazards. Furthermore, draft proposed edits to the PPS released for consultation

in 2019 suggest the need for municipalities to “prepare for the impacts of a changing climate” (see Section 5.2.1).

Climate change has the potential to alter watershed hydrology, such that existing hydrologic procedures, analyses and modelling may require adjustments or adaptations to adequately represent the range of potential hydrologic effects and to support modelling of affected flows and levels using hydraulic analyses to inform floodplain mapping. The MNRF’s Technical Guide – River & Stream Systems: Flooding Hazard Limit, which is used to help implement the PPS, was approved in 2002 and does not include the latest information on climate change. In recent years, there have been substantive changes in technology and an enhanced understanding of climate change considerations with regards to hydrologic modelling and associated influences on the hydraulic analyses required to develop floodplain mapping.

Existing policies and technical guidelines provide very little guidance on how to incorporate climate change consideration into planning and permitting decisions. Background work to derive options for integrating climate change considerations into the MNRF’s technical guidance has been ongoing since 2016 and would be integral to an update of the flooding technical guidance.

In 2017, the MNRF commissioned a study that produced a report titled: “Flooding Hazard Climate Change Advisory and Option Report.” The report identified ways in which climate change considerations can be integrated into the Technical Guide - River and Stream Systems: Flood Hazard Limit. Deliverables from this project will make significant contributions to ensuring that a range of options for addressing climate change and climate change adaptation that are consistent with provincial policy are available for consideration as the MNRF works towards enhancing implementation of Ontario’s existing flood hazard policies, while best addressing future climate considerations.

The MNRF (Water Resources Section) currently sits on the Steering Committee of a Natural Resources Canada funded study that will develop climate change information on future ice conditions and storm extremes for use in coastal infrastructure development, policies, programs and practices on the Great Lakes. Findings and data generated by this study will help inform updates to the MNRF’s technical guidance for the Great Lakes and connecting channels related to flooding, erosion and dynamic beach. Recent high levels and associated erosion on Lake Erie and Lake Ontario (specific areas of focus for the study), make the results of this study particularly timely.

6.1.1.2 Climate Change Resiliency of Existing Flood Standards

Flood standards specified in the MNRF's technical guidance for rivers and streams are based on the greater of the 100-year flood (which forms the minimum standard), floods produced by a specified meteorological event (e.g. Hurricane Hazel or Timmins Storm) or an observed flood greater than the 100-year flood level. Presently, little guidance exists for developing future climate informed flood standards, particularly for river and streams. While some have suggested incorporating arbitrary freeboard in floodplain mapping to account for uncertainty as a qualitative approach for assessing the uncertainties of flood impacts from climate change, little substantive information is available in the published literature, or in use by other jurisdictions to support this approach from a scientific perspective. Acknowledging this gap, the Flooding Hazard Climate Change Advisory and Options Report commissioned by the MNRF in 2017 also included considerations of a range of options for integrating climate change considerations to inform Ontario's flood standards.

6.1.1.3 Outdated Guidance on Floodproofing Standards

Floodproofing standards are currently addressed in the MNRF's Technical Guide – River & Stream Systems: Flooding Hazard Limit. Floodproofing information and standards identified therein are based on science and approaches from the 1980s. Floodproofing as addressed in the Technical Guide includes considerations of types of floodproofing, sound engineering practice related to construction and structural integrity, vehicular access considerations, and additional aspects related to flooding as a threat to life, including general rules regarding independent and combined functions of depth and velocity to support safe access and egress, and safe movement for most individuals in flood waters.

Work is wrapping up on an investigation and synthesis of current best practices, procedures, methodologies and technical considerations related to the field of floodproofing to protect people and property from flooding related natural hazards. This includes an evaluation of guidance presented in "Appendix 6 – Floodproofing" of the MNRF's Technical Guide – River & Stream Systems: Flooding Hazard Limit in the context of current and up-to-date protocols, procedures, methodologies and technical considerations. The evaluation will further include flooding as a threat to life to identify gaps and/or areas in the Technical Guide to highlight where the currency of the existing document would benefit from modifications and/or updates. A key deliverable is the development of considerations outlining appropriate options for updating the floodproofing guidance to support a revised Appendix 6.

Based on findings of background research and evaluation relative to the existing Technical Guide, the MNRF is considering producing a report proposing technical

information requirements, specifications and standards related to floodproofing to enhance the currency of techniques and technical considerations, and promote consistency in the application of floodproofing measures across the province.

This floodproofing review has implications for other MNRF natural hazard technical guides that refer to floodproofing (i.e. Great Lakes St. Lawrence flooding, erosion and dynamic beach) and has linkages to aspects of other policies and legislation such as the Ontario Building Code and the PPS documentation. Endorsement of newer methods could provide an additional range of options for Ontarians to manage and mitigate the impacts of flooding on dwellings.

6.1.1.4 Outdated Guidance on Hydrologic and Hydraulic Modelling

The hydrology and hydraulic chapters of the Technical Guide – River & Stream Systems: Flooding Hazard Limit are considerably dated. This includes reference to obsolete modelling software and to a lesser extent, standard practices.

The MNRF has completed initial research to identify methods and options for updating the sections associated with hydrology and hydraulics in the Technical Guide to account for technological and methodological advancements. With regards to hydrologic modelling, this includes an assessment of technologies and modelling protocols, practices and platforms for informing water level computations and flood line delineation, addressing the types of hydrologic models, model selection and calibration.

With regards to hydraulics, efforts included analyses to support improving the suitability of hydraulic analyses for estimating water levels throughout a wide range of rivers and river characteristics within Ontario. This involved guidance around choosing a hydraulic modelling technique, and direction around the use and applicability of 2-dimensional (2D) modelling, including guidance and standards for its use and interpretation. Guidance and requirements related to hydraulic model calibration, testing and sensitivity analysis were included, as were additional guidance on evaluating uncertainty in model parameters and the resulting impacts on model simulations and the associated range of error in modelled results.

While the above focus is on the riverine flooding guidance, the Great Lakes St. Lawrence and Large Inland Lakes guidance suffers from similar issues. Less effort has been placed on these documents.

6.1.1.5 Outdated Guidance on Surveying and Mapping Standards

In 1986, the MNRF adopted flood-related survey and mapping standards based on guidelines developed by the federal government under the cost shared Federal/Provincial Flood Damage Reduction Program, which ran from 1977 to 1992.

In 2002, to support municipal implementation of the PPS, the MNRF consolidated, developed and approved a series of natural hazards technical guides including the Technical Guide – River & Stream Systems: Flooding Hazard Limit.

In the Flooding Hazard Limit Guide, there is a placeholder: Section J, “Surveys and Mapping”, for new provincial direction on mapping standards and techniques.

Given the MNRF 1986 guidance is out of date, current mapping practice by municipalities and conservation authorities is to use best professional engineering judgement. Substantive advancements continue to be made rapidly in surveying and mapping standards and data acquisition, including in the areas of remote sensing, geomatics and mapping technologies and practices as discussed in other sections of this report.

With the recent release of the Federal Geomatics Guidelines for Flood Mapping, as part of the Federal Flood Mapping Guidelines Series, there is an opportunity to glean information from this document which may serve Ontario well and align, where suitable, the geospatial data requirements for flood modelling and mapping (go to <https://www.publicsafety.gc.ca/cnt/mrgnc-mngmnt/dsstr-prvntn-mtqtn/ndmp/fldpln-mppng-en.aspx>).

Updated standards are required to ensure consistency and adequacy of floodplain mapping across the province. The MNRF commissioned a review of jurisdictional surveying and mapping standards for flood mapping in 2016 and is in the process of evaluating options for updates to the appendix. A document titled: “Survey and Mapping Specifications and Standards Report” produced in 2018 for the MNRF was reviewed internally by the Ontario Public Service Elevation Coordination and Consultation Committee. This Committee brings together elevation experts from all relevant ministries and partner agencies to provide coordination and expertise on elevation data-related projects, acquisitions and issues. Feedback, technical comments and edits provided by this group are being incorporated into a final draft document, including considerations noted above related to the federal geomatics guidelines.

6.1.1.6 Other Policy or Technical Gaps

Other gaps in provincial policies and technical guidelines include:

- Lack of policy direction/technical guidance regarding drought. While the topic of drought is outside the scope of this review, it needs to be considered in the context of lowering reservoirs to capture more water and reduce the impacts of flooding, and whether a subsequent drought will prevent the reservoir from being refilled.
- Direction around the use of 2-dimensional (2D) and/or combined 1-dimensional/2-dimensional (1D/2D) hydraulic models. For example, is it necessary to consider floodplain storage in flood hazard mapping, and if so, which is the appropriate model.

Filling some of these gaps could help streamline approval processes by providing greater clarity and certainty around how to address these issues.

6.1.1.7 Limited Training, Outreach and Awareness

Limited provincial resources are currently directed towards training, outreach and awareness of the MNRF's policies, technical standards and guidelines. Such outreach is typically limited to ad hoc requests for presentations to various groups or events (e.g. annual conferences, workshops).

Limited training, outreach and awareness can contribute to misunderstanding, competing interpretations, and a lack of clarity and consistency in standards and policy requirements. Some stakeholders, including the Association of Municipalities of Ontario, have requested increased training and outreach with municipalities, developers and conservation authorities on the basis that it would help ensure services were undertaken more consistently across the province.

6.1.2 Policies, Standards, Regulations and Legislation

In her 2017 report, Ontario's Auditor General raised the following concerns:

"The provincial emergency management program does not focus on all five components of emergency management: prevention, mitigation, preparedness, response and recovery. Currently, the focus of the emergency management program in Ontario is mainly on only two of the five components—preparedness and response—with the Ministry of Municipal Affairs also undertaking activities related to recovery through the disaster financial assistance programs", (2017 Annual Report Volume 1, Office of the Auditor General of Ontario,

http://www.auditor.on.ca/en/content/annualreports/arreports/en17/v1_304en17.pdf).

While these concerns apply to the province's overall approach to emergency management, they may also apply to the province's approach to flooding.

Prevention-based approaches have been repeatedly shown to be more effective in reducing the impacts of flooding and other natural hazards. As outlined within the five core components of emergency management, flood prevention relies on the use of non-structural measures, such as land use planning and permitting and building controls to keep people and property out of hazardous areas. In Ontario, land use restrictions are put in place by municipalities to prevent new or intensified development in areas prone to flooding and other natural hazards. Land use restrictions are also put in place by conservation authorities who are required to regulate development (in areas prone to natural hazards) for impacts to the control of natural hazards as set out in regulation (i.e. flooding and erosion) and for interference with a watercourse or a wetland.

While regulations and land use restrictions have been in place for a few decades in Ontario, concerns have been raised noting that these policies and associated technical requirements may not be adequately enforced and too easily ignored in response to the financial incentives or other incentives (such as infill development in historic communities) that encourage new and intensified development in or adjacent to flood-prone areas. These incentives often encourage greater reliance on tools contained within other core components of the emergency management framework, such as the use of mitigation measures (e.g. flood protection berms, floodproofing), preparedness systems (e.g. flood warning systems), and response (e.g. temporary sandbag dikes) and recovery programs (e.g. disaster assistance and/or insurance) that do not require strict adherence to a prevention-first approach to managing the impacts of flooding.

Clearly, more focus on prevention is needed, and strengthening existing policies and standards by enshrining them in legislation (or by regulation) is required.

As mentioned in Section 5.2.2, the MNRF is proposing a regulation under the *Conservation Authorities Act* that outlines how conservation authorities regulate development and other activities for impacts to the control of natural hazards and public safety. The proposed regulation will make rules for development in hazardous areas more consistent to support faster, more predictable and less costly approvals.

Recommendation #1

That the MNRF proceed as expeditiously as possible to finalize its proposed regulation under the *Conservation Authorities Act* and submit it to Cabinet for approval.

6.1.2.1 Consideration of Risk in Floodplain Management Policies

There are two main approaches to managing flooding and other natural hazards: a hazards-based approach and a risk-based approach.

A hazards-based approach focuses on determining where hazards exist and then taking steps to prevent activities from occurring in those areas. A risk-based approach focuses on determining the risks posed by natural hazards, and then taking steps to further reduce those risks to acceptable levels. In the case of flooding, a hazards-based approach seeks to delineate the floodplain and prevent development from occurring within it. A risk-based approach seeks to identify the risks associated with development in a floodplain and find ways to reduce those risks through enhanced floodproofing, flood forecasting and warning, and other measures. Adopting a risk-based approach allows individuals to proceed with a given activity (e.g. development within a floodplain) provided that sufficient measures can be put in place to keep risks as low as reasonably achievable.

While there is some support for a risk-based approach, developing and successfully rolling out a risk-based planning and/or permitting framework would be a complex and resource-intensive task requiring new provincial policy direction in several areas including defining acceptable levels of risk.

The MNRF's current approach to managing flooding and other natural hazards straddles these two approaches by taking a hazards-based approach to limiting new development and taking a risk-based approach to reduce risks associated with existing development located in hazardous areas (e.g. as with Special Policy Areas). Risk-based flexibility is also provided for development in the flood fringe in areas where the two-zone concept is applied, subject to floodproofing consistent with MNRF standards. This seems to be at odds with what some conservation authorities believe, as they have advocated for taking a risk-based approach to mitigate urban flood risk. They recommend that the Province contemplate how to incorporate a consideration of risk when updating floodplain implementation guidelines.

Recommendation #2

That the MNRF consult with the conservation authorities on their application of the hazards-based approach and the risk-based approach to managing flooding.

6.1.2.2 Provincial Policy Statement Review – Proposed Policies

Overall, I am in agreement with the existing policies under the Provincial Policy Statement (PPS) Review, in particular with Section 3.0 Protecting Public Health and Safety. This Special Advisor on Flooding report covers some of the content in the PPS Review, which is based on my review of a considerable amount of background information, what I heard while meeting with municipalities and conservation authorities, and from submissions received by municipalities, CAs and other agencies. The proposed PPS policies are supported by some of the recommendations I've made in this report, such as the need for updated technical guidelines; entrenching elements of the technical guides (such as standards) in legislation; and reviewing and updating the MNRF's technical guides to support the use of flood protection landforms.

Recommendation #3

That the following be incorporated into the Provincial Policy Statement:

- The reference to “impacts of a changing climate” throughout the Provincial Policy Statement helps to bring it to everyone’s attention and should be included in the Preamble as well.
- Either in the body of the PPS or in the definitions section, reference should be made specifically to the requirement for conservation authorities to regulate development activities in hazardous lands as required in the *Conservation Authorities Act*.
- That “d) Transportation and Infrastructure Corridors, Airports, Solid and Liquid Waste Management” be added to Section 3.1.5 of the Provincial Policy Statement.

6.1.3 Floodplain and Flood Risk Mapping

Having accurate floodplain maps help communities make efficient and effective planning decisions. The Office of the Auditor General suggests that up-to-date floodplain maps would allow municipalities to better plan for future growth in areas of low flood risk, and build infrastructure and resiliency in high-risk flood areas.

6.1.3.1 Limitations of Existing Geomatic Data and Mapping

The management of floodplains and other hazardous areas begins with their identification. Knowing the location of these areas can help streamline approval decisions and ensure areas not subject to flooding and other natural hazards can be developed.

Several issues exist associated with data and mapping used to delineate floodplains and other areas. CAs report that a large percentage of their floodplain mapping require some form of an update. This takes into consideration all elements of floodplain mapping, including the age, limitations and accuracy—not just the currency of existing mapping alone. It is important to note that particularly in areas of the province where development pressures are low, age of mapping is not necessarily an indicator that mapping is out-of-date or “outdated.”

6.1.3.2 Updates to Floodplain Data and Mapping

The cost of updating floodplain mapping can be prohibitive to municipalities and CAs, as it requires high resolution elevation data.

Recent base data acquisitions funded by the Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA) and in partnership with the MNRF, including the use of Light Detection and Ranging (LiDAR) technology, have significantly reduced the cost burden to CAs and municipalities associated with base data acquisition, particularly in south-central and southwestern Ontario.

Considerable work has been undertaken by municipalities and conservation authorities in the province over the last several years to update floodplain mapping with matched federal funding provided through the federal government’s competitive, merit-based National Disaster Mitigation Program (NDMP). Flood mapping was a specific funding stream of NDMP. Under NDMP, only applications related to the municipal land use planning and mitigation were eligible, and projects related to CA regulatory limit mapping to support the implementation of conservation authority regulations made under the *Conservation Authorities Act* were not eligible. The Province included a specific requirement for conservation authority proposals— that municipal support for the project be demonstrated through a letter of support from the affected municipality or municipalities (including regional governments). Furthermore, if the conservation authority planned to use a municipal levy to cover project costs, that the letter of support must also reference the municipalities support for the levy funding mechanism. By way of the letter of support, municipalities were also required to commit to the flood mapping being integrated into Official Plans to guide future development outside of flood-prone areas.

From 2015 to 2019, municipalities and conservation authorities received approximately \$9 million towards updating flood maps across Ontario, for a total investment of at least \$18 million in flood mapping.

Across all five NDMP intakes and all four funding streams, a total of \$40.58 million in federal funding was secured by Ontario applicants. Including applicant matched funding, this means that no less than \$81 million in total funding has been secured for flood-related initiatives through all five intakes of NDMP.

6.1.3.3 Expanding Regulatory Flood Lines

Many factors can contribute to the expansion of regulatory flood lines. These lines are dynamic in nature and can expand and move as development in the watershed changes, altering rainfall-runoff characteristics and associated flood generation. Land use change can contribute to larger amounts of water being more quickly delivered to streams and rivers. The larger volume of water in rivers and streams acts to expand flood lines, covering larger areas of land adjoining streams and rivers with water under the flood standard. In addition, acquisition of new and more accurate survey and mapping data combined with revised hydrologic and hydraulic modelling can result in considerable differences in the extent of regulatory flood lines between current and updated flood hazard mapping, particularly when based on full build-out projections related to a 20-year official plan.

Regulatory flood lines and associated floodplains are expanding or are expected to expand, bringing more existing development, and areas targeted for new development, into flood-prone areas. This can be particularly true in areas using a 1:100-year storm event to delineate regulatory flood lines; however, areas currently using a 1:250-year storm event (e.g. areas within the Upper Thames River watershed) are also finding significant expansions in regulatory flood lines. Areas using a regional regulatory storm (i.e. Hurricane Hazel or the Timmins Storm) are less likely to see significant increases in the size of regulated floodplains as these events have higher return periods (lower chance of occurring).

Regulatory flood lines and floodplain mapping should be updated along with updates to municipal official plans. It is important that flood hazard identification incorporated into municipal planning documents, through mapping or otherwise, reflect a full build-out condition of the upstream watershed based on the current official plan. This level of rigour is intended to provide people and property downstream a level of assurance that flood hazards are accounted for, and that the influence of future land development on flooding is considered. As this mapping is used by municipalities for land use planning purposes, mapping is generally current until the next Official Plan update and based on a (+/-) 20-year planning horizon.

Many areas of southern and southwestern Ontario have experienced and continue to experience rapid urban development. Many municipalities have been highlighting the need to update flood hazard mapping to capture the effects of land use development occurring since mapping was last completed and to use the most current data and technologies (i.e. LiDAR, 2D hydraulic modelling where appropriate, etc.).

Expansion of regulatory flood lines can be a concern for municipalities, developers and existing homeowners regarding the impacts of expanded lines on future growth opportunities, the ability to invest in and protect existing homes, and property values. To date, 73 flood mapping projects across southern Ontario have been funded by the federal National Disaster Mitigation Program (NDMP) with the aim of updating existing floodplain mapping across more than 30 municipalities. These studies could result in expanded regulatory flood lines, and associated concerns from the development community and others regarding the potential impacts of updated flood lines on existing and planned development within these municipalities.

Increased urbanization, exacerbated by the influences of a changing climate, can create a situation whereby areas that were considered to be outside of the floodplain, and managed and developed without specific consideration of the flood hazard, may be subject to a greater flood hazard and associated flood inundation. To better understand how this issue is being addressed internationally to provide context on how Ontario may approach them in the future, the MNRF commissioned a jurisdictional analysis of expanding floodplains in a policy and planning context. A scan of the literature conducted early in the project revealed that most jurisdictions have moved beyond a regulatory hazard-based approach to defining and managing regulatory flood lines, and instead now focus on managing floods in-line with a risk-based approach. Most international jurisdictions, rather than using a single likelihood of flood hazard to define flood lines and the flooding hazard limit, have transitioned to consideration of multiple likelihoods, and also of the number and type of exposed elements in the floodplain.

The project therefore focused on considerations for supporting the adoption of a risk-based management approach for riverine and lake flooding in Ontario, including approaches and opportunities for managing changing flood lines, with a view to understanding and managing flood risks in the context of Ontario's policy and planning landscape.

6.1.3.4 Technical Guidance That Governs Floodplain Mapping

While the Mapping and Geomatics Services Section of the Mapping and Information Resources Branch of the MNRF has been able to provide guidance on LiDAR acquisitions and the management of legacy datasets to other provincial agencies, recent projects under the National Disaster Mitigation Program (NDMP) have supported

LiDAR acquisitions by municipalities and CAs on a project-by-project basis. Ontario does not have defined flood survey and mapping guidance or standards available to support consistent survey data acquisition and mapping by conservation authorities, municipalities and developers. Updated technical guidance is needed to determine what level of detail is required for floodplain mapping and how these expectations may differ in rural or urban areas.

This lack of coordination has led to gaps in coverage for many areas of the province; duplication of effort; inconsistent data standards and data access; and increased costs.

Technology, tools and approaches to deliver modern digital floodplain mapping have changed since the most recent update of floodplain mapping technical and implementation guidelines was last completed in 2002. Work recently commissioned by the MNRF to develop surveying and mapping specifications, and standards for flood hazard mapping (in support of an update to the natural hazard technical guides), will make considerable headway in advancing mapping consistency across the province.

A couple of conservation authorities have reported that new technologies and approaches have been piloted or developed amongst the conservation authority community along with CA guidelines for developing new digital floodplain mapping. Case studies and CA guidelines can be provided by the CA community to assist the Province with assessing the new approaches and developing the new provincial guidelines for hazard and flood risk mapping. They have even offered secondments of CA personnel to the MNRF to help transfer knowledge and experience, and to create a collaborative approach to updating the technical guidelines.

Recommendation #4

That the MNRF update floodplain mapping technical and implementation guidelines recognizing new technology and approaches for flood hazard and flood risk mapping, and that the MNRF collaborate with conservation authorities on this initiative.

Recommendation #5

That the Province update its technical guides pertaining to floods and natural hazards. This should include undertaking a review of the flood event standards (e.g. 1%, Timmins storm, Hurricane Hazel), with a view to providing for current science and climate change, such as a specified minimum freeboard. This should also include reviewing the floodplain areas (floodway, floodway fringe, shoreline setbacks) as well as reviewing and updating, where appropriate, Great Lakes flood level values and shoreline erosion hazard methodologies and allowances.

6.1.3.5 Costs Associated with Updating Floodplain Mapping

In 2013, Conservation Ontario estimated that a one-time investment of \$24.8 million was required to update floodplain mapping and modelling in Ontario for areas where CAs have been established. A study on floodplain mapping commissioned by Public Safety Canada estimated that the costs of mapping currently unmapped floodplains in Ontario could be as high as \$119.6 million (2014). More recently, in 2017, Conservation Ontario estimated the cost of an update being approximately \$136 million; however, it is not clear if this cost only includes areas of the province where conservation authorities have been created.

The National Disaster Mitigation Program (NDMP) was an effective federal program that provided 50% funding to complete updated floodplain mapping. That program ends in March 2020. Either a new federal or provincial, or combination of a federal/provincial program could provide the necessary funding.

The federal government continues to advocate and encourage adaptation and preparedness for climate variability. One of the most practical adaptations is emergency preparedness and response plans, which help make communities more resilient to climate change. Floodplain mapping and the associated models supporting floodplain mapping are fundamental to the creation of effective emergency preparedness plans for floods. A case could be made to the federal government to fund the creation of modern digital floodplain mapping as adaptation and preparedness for climate change and severe weather events.

It has been suggested that the Province discuss the opportunity to take a strategic, multi-year, multi-agency planning approach to an extended program, in order to address known gaps in floodplain mapping. As currently established, the National Disaster Mitigation Program (NDMP) is based on interested parties applying for funding. It has also been suggested that the Province advocate to the federal government for continued funding of the NDMP or development of a successor program, recommending the end date of the program be extended for 10 years, from March 2020 to March 2030. As such, the federal government investment in floodplain mapping would help achieve its goal of encouraging adaptation in preparation for climate change and extreme weather events.

Recommendation #6

That the Province establish a working group with provincial departments, conservation authorities and municipalities to prepare a multi-year approach to floodplain mapping.

Recommendation #7

That the federal government be encouraged to extend the National Disaster Mitigation Program or develop a successor program, so that municipalities, conservation authorities, and Ontario and Quebec (in consideration of the Ottawa River) can undertake or update floodplain mapping in all critical areas.

6.1.3.6 Proposed Elevation Mapping Program

Regardless of whether the federal government extends the NDMP, there is a need to establish an Elevation Mapping Program within the MNR's Mapping and Geomatics Services Section. This program will ensure more complete coverage of the province; centrally manage a cross-agency funding model; leverage existing multi-ministry governance and budgeting capacity of the Land Information Ontario (LIO) program; reduce total costs and bureaucracy for all provincial agencies; consider cross-discipline business requirements; allow for consistent standards to be collected; align with other provincial, state and national elevation programs (Manitoba, Quebec and New Brunswick, Canada and the United States); centrally manage elevation data procurement, quality control, data management and data distribution; and leverage staff knowledge and skills to address future changes in acquisition requirements and technology (e.g. bathymetric LiDAR).

Establishing an Elevation Mapping Program will align with current government priorities:

- Ontario's Open Data Directive by maximizing access to government data;
- Ontario's Data Integration Initiative by supporting standards for data management, and releasing non-sensitive government data to promote transparency, spur innovation and economic growth; and
- Ontario's Digital and Data Task Force driving innovation using emerging data technologies.

This program would require net-new annual funding for data acquisition and for data storage and distribution.

Recommendation #8

That the Province consider the establishment of a provincial Elevation Mapping Program and commit to the annual funding requirements.

6.1.3.7 Provincial Custodian for Floodplain Mapping Information

LiDAR data is a modern approach and an important component of producing floodplain maps. It is expensive but can be affordable if two or more agencies team up to acquire the data. The Mapping and Geomatics Services Section (MGSS) of the Mapping and Information Resources Branch of the MNR has a multi-year program for planned topographic LiDAR data acquisitions within southern Ontario. The program is intended to assist with identification of priority areas for future data collection, and to reduce duplication of effort by identifying where data may have already been collected or is planned to be collected by other government agencies.

Engagement with municipal, conservation authorities, and provincial and federal agencies has identified that flood mapping information (geospatial data, reports, and flood maps) created through the historic Federal Damage Reduction Program (FDRP) and National Disaster Mitigation Program (NDMP) projects are not seamlessly and centrally managed or accessible. On the latter point, some mapping has been acquired on the vendor's condition of restricted access only by the client.

The lack of a consolidated data management solution for flood mapping data is resulting in: 1) inability for provincial programs to incorporate data into their operations, including emergency management and response; 2) increased risk of data loss; 3) inconsistent data standards; and 4) inability to reference the data for LiDAR acquisition planning. Accordingly, there is a need to identify a provincial custodian for flood mapping information in order to clarify data ownership; determine requirements for data management, storage and access; and leverage Land Information Ontario's existing geospatial infrastructure to support data maintenance, access and dissemination at minimized costs.

If a single provincial custodian is to be established, consideration would need to be made for ownership (intellectual property) of the flood mapping information, as it is mainly held by municipalities. Policy, regulations and legislation would likely need to be updated to identify a requirement for all provincial agencies to provide flood mapping information up to the provincial custodian. Some municipalities and CAs are moving to new Open Data standards and publishing regulatory flood lines on their websites. Policy, regulations and legislation would also likely need to be updated to require that floodplain maps produced at the local level are provided to and integrated into a common provincial floodplain map repository.

Recommendation #9

That the Province consider establishing a provincial custodian for floodplain mapping information and make the necessary updates to policies, regulations and legislation.

6.1.4 Roles and Responsibilities

Several different agencies share roles and responsibilities for the management of flooding and other natural hazards. The reality is that some prevention, mitigation, preparedness and response roles have to be shared between municipalities and multiple ministries by nature of the services they provide.

However, it was pointed out at some of the municipal engagement sessions, that when roles and responsibilities are shared amongst several different agencies, it diffuses control, expertise, and ultimate decision-making and accountability among the agencies.

6.1.4.1 Unclear Roles in Emergency Management

Chapter 3 of the 2017 Auditor General's Annual report raised concerns regarding the current governance structure for emergency management noting that:

“The current governance structure for emergency management in Ontario is not effective for overseeing a province-wide program. Oversight of emergency management in Ontario is the responsibility of the Cabinet Committee on Emergency Management. However, this committee has not met for several years. Concerns about the overall oversight of emergency management in the province were brought to the government’s attention as far back as 2005 in an internal review report, Emergency Management Processes in the Ontario Public Service. The report concluded: At the enterprise level, processes are not currently sufficient to ensure that Ontarians and the resources of the Province are adequately protected against emergencies and disasters.” (2017 Annual Report Volume 1, Office of the Auditor General of Ontario, http://www.auditor.on.ca/en/content/annualreports/arreports/en17/v1_304en17.pdf).

While the report focused on the broader umbrella of emergency management, similar concerns could apply specifically to the management of flooding and other natural hazards.

The Office of the Fire Marshall and Emergency Management (OFMEM) within the Ministry of the Solicitor General is taking action to address the Auditor General’s

recommendations and other reviews. Following is a summary of some of the initiatives planned or currently underway:

- AG recommendation to strengthen Emergency Management and Oversight – Emergency Management Ontario (EMO) will establish inter-ministerial and a multi-level governance framework (e.g. Cabinet Committee on Emergency Management) to support decision-making, collaboration and information sharing.
- AG recommendation to update all risk assessments and response plans – EMO to review existing provincial risk assessments and the provincial emergency response plan; and re-establish province-wide Continuity of Operations Program and directly support development of municipal continuity programs.

Recommendation #10

That the Ministry of the Solicitor General implement the Auditor General's recommendations regarding a governance framework for emergency management and updating continuity of operations programs as soon as possible

6.1.4.2 Unclear Roles and Responsibilities for Identifying Hazardous Areas

While the MNRF generally takes the position that municipalities are exclusively responsible for identifying hazardous areas, provincial policy is unclear and at times contradictory, and has created some confusion over who is responsible for identifying hazardous areas.

The Emergency Management and Civil Protection Act, 2009 (EMCPA) requires both provincial ministries and municipalities to identify and assess the various hazards and risks to public safety that could give rise to emergencies.

Section 2.1(3) regarding municipalities states: "In developing its emergency management program, every municipality shall identify and assess the various hazards and risks to public safety that could give rise to emergencies and identify the facilities and other elements of the infrastructure that are at risk of being affected by emergencies." 2002, c.14, s.4.

Section 5.1(2) regarding provincial ministries states: "In developing an emergency management program, every minister of the Crown and every designated agency, board, commission and other branch of government shall identify and assess the various hazards and risks to public safety that could give rise to emergencies and identify the facilities and other elements of the

infrastructure for which the minister or agency, board, commission or branch is responsible that are at risk of being affected by emergencies.”

Provincial guidelines direct municipalities to identify floodplains and other hazardous lands to incorporate these areas into their Official Plans, plan amendments, zoning bylaws and associated approvals. Municipal planning authorities, under Section 3 of the PPS (2014), are to direct development to areas outside of hazardous lands (including the floodplain identified by the limit of the flooding hazard). As per the preface of the MNR's Technical Guide – River and Stream Systems: Flooding Hazard Limit (2002), the Province has empowered municipalities to assume responsibilities for the management of flood risk areas, and the associated liability and the risk relative to planning for new land uses in and around these areas.

Conservation authorities also invest with provincial and municipal funding in identifying hazardous areas for carrying out their delegated role in reviewing municipal planning documents for consistency with the PPS and to support administering their regulation. While the MNR is responsible for identifying hazardous areas in areas where no municipalities or CAs have been established, some municipalities advocate that this responsibility should extend to any area where a CA has not been established and that expecting municipalities to identify hazardous areas places an unrealistic burden on small, rural municipalities.

Municipalities can choose to rely on the services of CAs to undertake floodplain mapping but are not required to do so. While some municipalities and conservation authorities partner together to create maps, others do not. In these cases, municipalities contract consulting engineering firms to complete the floodplain mapping work, as do CAs in some instances.

Recommendation #11

That the Province consider whether the *Emergency Management and Civil Protection Act* needs to be amended with a view to clarifying roles and responsibilities of identifying hazardous areas.

Recommendation #12

That the MNR consider working with Conservation Ontario and the Association of Municipalities of Ontario to determine how the experience and information developed by municipalities and conservation authorities of identifying hazardous areas can be transferred to municipalities without a conservation authority.

6.1.4.3 Conflicting Policy Direction and Technical Advice

Shared roles and responsibilities can lead to conflicts over provincial policy direction when multiple agencies have differing perspectives on a given issue, and where other agencies are creating and disseminating guidance materials that are not consistent with MNRF endorsed policy or technical guidelines.

The MNRF provides policy direction and technical guidelines to municipalities and conservation authorities to support their planning and regulatory roles. Many CAs have their own policies in place that, at times, are used to supersede or are seen to contradict provincial policy and technical guidelines.

Some conservation authorities and municipalities view technical guidance provided by the MNRF as simply guidance to be used by engineers and other professionals to help guide their decisions, and allowing them to apply their own policies or professional judgement to decide.

Additional technical guidelines concerning the management of flooding and other natural hazards, although not necessarily provincially endorsed are also prepared and released by academia, the Standards Council of Canada, and the National Research Council.

There is no specific recommendation to deal with this issue as other recommendations provided in this report, such as enshrining flood hazard policies and technical standards in legislation, if adopted, should take care of the conflicting policy direction and technical advice.

6.1.4.4 Conflicts Between Planning and Permitting Decisions

While municipal planning and conservation authority permitting processes are related, they are distinct processes with distinct requirements.

Differences between planning and permitting requirements were noted by some stakeholders as causing conflicts between regulatory and municipal planning decisions. Some stakeholders commenting during the review questioned the ability of a CA to refuse an approval for projects previously approved under the *Planning Act*. Similar concerns have been raised regarding the pressures placed on municipalities, the Province and CAs in balancing growth and the management of hazards, particularly in municipalities with very specific growth targets.

Recommendation #13

That the Province consider legislative amendments that clarify the permissions under the *Conservation Authority Act* and the land use approvals in accordance with the *Planning Act* as they relate to development in hazardous areas.

6.1.4.5 Perceived Conflicts of Interest

Municipalities are ultimately responsible for making local planning decisions. Some stakeholders have raised concerns that this creates a conflict of interest for municipalities, as there is a perceived financial incentive not to limit development in areas prone to flooding and other natural hazards, despite potential future recovery and relief costs.

Some sectors have raised concerns that members of a conservation authority, who are primarily municipal officials, were pressured to approve projects that are deemed to be “in the interest of” municipalities, and that the lack of clarity and consistency in requirements made it difficult for a CA to say no to proposals that member municipalities want, particularly if they feel as though that decision may risk future funding.

Again, there is no specific recommendation to deal with this issue as other recommendations provided in this report, such as enshrining flood hazard policies and technical standards in legislation, if adopted, should take care of the perceived conflict of interest.

6.1.4.6 Role of the Provincial One Window Planning Service

The provincial One Window Planning Service is the organizational structure and process established to support the move to a policy-led land use planning system. It entails the Ministry of Municipal Affairs and Housing (MMAH), in consultation with partner ministries and, where applicable, conservation authorities under their MNRF delegated role, providing municipalities, planning boards, development applicants and the public with “one-stop” access for provincial land use planning services, with a focus on where MMAH exercises its statutory functions under the *Planning Act*.

Under the provincial One Window Protocol and an associated memorandum of understanding, MMAH consults with conservation authorities regarding natural hazard impacts of policy and development proposals for which it is the decision maker. Where no conservation authority has been established, the MNRF undertakes this review. Municipal planning documents approved by MMAH include all upper-tier and single-tier Official Plans (OPs), and some upper-tier and single-tier Official Plan Amendments

(OPAs). MMAH is also the decision-maker for applications from territory without municipal organization where there is no planning board. Under the provincial One Window Protocol, the Minister of Municipal Affairs and Housing is the only provincial minister who can appeal municipal planning decisions to the Local Planning Appeal Tribunal. In some circumstances, public bodies, including conservation authorities, that provided comments before a municipal decision was made can also appeal municipal planning decisions.

6.1.4.7 The Federal Government

The release of the Federal Flood Mapping Guideline Series has created confusion on the flood modelling and mapping landscape of Ontario and other provinces/territories, related to roles and responsibilities between the provinces and the federal government. The incorrect assumption among some practitioners is that the federal “guidelines” supersede those of the province. However, this series of federal documents does not replace or supersede any provincial legislation, technical standards, policy or assigned roles and responsibilities of provincial and municipal governments and their agencies in natural hazard management and mitigation. The development and implementation of flood management legislation, regulation, standards, policy and flood mitigation measures is primarily a provincial/territorial responsibility.

The federal government may intend these federal guidelines as a basis for further specification as defined by a province. However, Ontario already has its “specifications” and will adopt what is pertinent to the province, through any subsequent updates that the MNRF makes to existing guidance. The overall confusion which seems to be exacerbated by each subsequent federal guideline release has resulted in engineering staff in MNRF’s regional offices needing to reaffirm the precedence of the MNRF’s natural hazard technical guides when working with proponents and consultants.

6.1.4.8 Provincial Watchdog

In many jurisdictions, there is a “provincial watchdog” role by a minister over a specific subject, area or discipline. The Ontario *Great Lakes Protection Act* legislative framework is a good example of what new legislation could be considered by the Province to improve the existing flood policy framework. As examples, the legislation could:

- Establish a lead minister for all flood related policy, standards, regulations and legislation.

- Establish the Minister of Natural Resources and Forestry, as the lead Minister given that the MNRF is already lead administrative ministry having overall government responsibility for hazard management policies/ programs.
- Direct that the Minister of Natural Resources and Forestry to work with the ministers responsible for the other Acts that touch on flooding (as identified in Section 5.2) on issues raised above and re-listed here:
 - Clarifying roles in emergency management;
 - Clarifying roles and responsibilities for identifying hazardous areas;
 - Clarifying policies;
 - Clarifying technical advice;
 - Eliminating conflicts between planning and permitting decisions;
 - Eliminating conflicts of interest;
 - Reviewing the role of the provincial One Window Planning Service and the appeal mechanism; and
 - Reinforcing that provincial guides, standards, etc., take precedence.
- Provide the lead minister with the authority to amend flood hazard related planning policies.
- Provide the lead minister with the authority to direct public bodies (including other ministries, municipalities, CAs, etc.) to carry out defined actions.

Recommendation #14

That the Province consider new legislation to improve the existing flood policy framework by having a lead minister responsible for all flood-related policy, standards, regulations and legislation.

6.1.4.9 Lack of Awareness of Property Owners

Often when floodplain properties are sold the seller isn't aware of, or doesn't openly disclose, the fact that the property is located in the floodplain nor the risk of flooding that is associated with the property. Disclosure is not required during real estate transactions. However, it was reported that financial institutions are now looking at the risk of providing mortgages to flood risk properties, and some real estate agents are disclosing the risk to protect their own liability. Even if this was being done everywhere,

it is too late in the process and potential home buyers should know up front before making an offer and applying for a mortgage.

Recommendation #15

That the Province consider adopting legislation that will require flood risk properties to be identified in some way that is publicly accessible, at the very least on the property title, to ensure that prospective buyers are aware.

6.2 Mitigation

As Ontario metropolitan areas continue to grow, they face increasing pressures to develop—by growing outward, through the construction of new communities at the urban fringe, and growing upward, by accommodating more residents in existing urban areas. Provincial policies such as those contained within “Growth Plan for the Greater Golden Horseshoe” (2006) as well as within the Provincial Policy Statement, include density targets and other policies designed to limit outward growth and the creation of urban sprawl, and to promote greater densification and infill development within existing built-up areas.

Across larger scales, limiting sprawl helps to mitigate increased flooding caused by development by maintaining natural and pervious surfaces within a watershed that help to reduce and slow stormwater runoff. At the same time, targets for increased densification and infill development places additional pressure on municipalities to utilize currently undeveloped areas in existing settlement areas, including floodplains and other hazardous areas, and increase densities in already developed areas that are located in hazardous areas due to historic settlement patterns, such as designated Special Policy Areas. In some instances, urban areas targeted for further intensification and growth may be partially, or wholly, within flood-prone areas.

6.2.1 Great Lakes/St. Lawrence River Shorelines

As discussed in Sections 4.6 and 4.7, the shorelines of the Great Lakes and the St. Lawrence River have and continue to be significantly impacted by very high lake levels and erosion.

It would be ideal if everyone lived, carried on a business or installed infrastructure (roads, water, sewer, etc.) far away from the edge of the shoreline, as shoreline erosion is a natural event, and occurs under both high and low water situations and in between. However, legacy development and conversions of quaint little cottages into primary residences has resulted in a very large number of properties being at risk. This is

exacerbated by the fact that there are neighborhoods with ground elevations below the shoreline and the current lake level.

Mitigation of shoreline erosion is a very complicated challenge. For areas of intense development, the common mitigation option is shoreline protection, such as dikes, erosion protection and shoreline stabilization. There are many different examples of these structures that exist today and some are more resilient than others. Of course, removing or moving structures further away from the shoreline is another option.

These mitigative measures are extremely expensive and sometimes can't protect to the water levels seen recently. Property owners are responsible for covering the cost of these works on private property, which is the same in many jurisdictions across Canada.

In Ontario (and similarly in other jurisdictions), municipalities may consider using local improvement charges (see Ontario Regulation 586/06 under the Municipal Act, 2001) to: first, assist with the construction and financing of a shoreline protection project for a group of private property owners (that may provide economy of scale for the design and construction of the works); and second, imposing a local improvement charge which may help make the financial commitment of the overall cost of the shoreline protection works on their property easier for the private property owner by spreading it out over 20 years or more.

Further, in the case of low-lying neighborhoods inland that rely on the protection works, the municipality could consider if charges might be included as part of the calculation of a larger benefitting area and therefore the cost of the works might be spread out among all benefitting properties, and not just the properties along the shoreline.

In my review of Ontario statutes, I discovered a piece of older legislation that is not currently used titled: *The Shoreline Property Assistance Act*. Under this legislation, the province may offer a Shoreline Property Assistance Program under which municipalities may issue debentures (subsequently purchased by the Treasurer of Ontario) to fund loans to private property owners to construct works such as retaining walls, dikes, breakwaters, groynes, cribs and other structures for the rehabilitation or protection of shorelines, including repairs and improvements to existing works. The funds may also be used by private property owners for raising, relocation or repairs to buildings. The Shoreline Property Assistance Program was cancelled by the Province in 2010 and not currently available to municipalities.

Municipalities may still consider offering loans to private property owners. One municipality in southwestern Ontario, the Town of Essex, has recently approved a new loan program for shoreline residents.

Recommendation #16

That municipalities consider utilizing local improvement charges to help finance and install (or upgrade) shoreline protection works, and if necessary, that the Province provide municipalities with enhanced authority to do so.

6.2.2 Ottawa River

6.2.2.1 Meteorological and Hydrological Conditions

The meteorological and hydrological conditions during the spring freshet period in the Ottawa River basin can vary widely and the inability to forecast, with any precision, mid-to-long term conditions presents an ongoing challenge. The storage capacity within the basin is finite and the goal of integrated management of the reservoirs is to effectively apply the use of reservoir storage to reduce downstream flows at the most critical periods of spring flooding. The appropriate use of the available storage is typically applied by reducing reservoir discharges during the periods when flows from the uncontrolled sectors of the basin are high (first peak) and then increasing discharges as this flow in the lower tributaries begins to decrease. The challenge then becomes one of increasing reservoir discharges, to prevent overfilling the storage reservoirs, but at the same time not causing downstream flow to exceed the initial peak.

Due to the topography of the Ottawa River basin, the use of reservoir storage in the upper part of the river has an exaggerated effect on reducing the first peak in the upper sections of the river (Mattawa-Pembroke) because of their proximity to the reservoirs. In years where the spring runoff in Abitibi-Timiskaming greatly exceeds the storage capacity of the principal reservoirs, a second peak along the lower river reach can occur. The area of the highest constriction on the river is below Pembroke in the Westmeath/Lac Coulonge area, and the effective use of reservoir storage in the Abitibi-Timiskaming area can be seen by two peaks that are close in size but both significantly lowered due to the use of reservoir storage. The basin topography and use of reservoir storage then often results in a second peak that is lower in the southern sections of the basin but higher in the more northerly sectors even though under natural conditions, without reservoir storage, the first peak would have been higher throughout. These are broad operational strategies that are impacted by the specific meteorological and hydrological conditions that vary significantly from year to year.

The uncontrolled/unregulated portion of the drainage basin contributed significantly to the flooding in both the 2017 and 2019 floods. For instance, in 2019, the Water Survey of Canada streamflow gauge on the Petawawa River, in operation since 1915, experienced its highest flow on record in April 2019, with a peak flow 46% higher than

its previous historic peak value recorded in April 1995. An analysis of flood magnitudes in the absence of existing water management structures and reservoirs (which regulate the other 40% of the drainage basin) was undertaken by the Ottawa River Regulation Planning Board following the 2017 flood. For example, results showed that under the 2017 flood at Lac Deschenes, water levels would have been approximately one metre higher had there been no dams or reservoirs within the Ottawa River drainage basin.

6.2.2.2 Existing Development in the Floodplain and Floodway

Many areas affected by flooding in 2019 (and 2017) were legacy development or development that predates Ontario's floodplain planning policies. Some of the more significantly affected areas in the vicinity of Westmeath, Rhoddy's Bay, Braeside and Constance Bay, among other areas, are generally situated within the floodplain of the Ottawa River under the 1% flood (pursuant to mapping prepared under the Canada-Ontario Flood Damage Reduction Program during the 1980s and early 1990s) and updated mapping completed by the municipalities and or a conservation authority (where available). Many of these areas are also mapped to be in the floodway, where flood depths exceed one metre and/or flow velocities above one metre per second can create significant hazards for developments.

Many of the dwellings that dot the landscape along the Ottawa River in the above noted villages and hamlets were once modest camps that were transitioned into seasonal cottages, and now many exist as permanent year-round residences. Significant investments have been made to these residences throughout the years; however, for the most part they are not flood proofed to the flood standard (1% flood).

While clearly unfortunate, it was not a surprise to see in person that many of the areas affected by flooding were very close to the river and there was a relatively small difference in elevation between the foundations (main floors) of many residences and the elevation of the river under normal water conditions in early September 2019. A tour of some areas provided evidence that some property owners were already in the process of raising their residences to a higher level and possibly some included moving their structures further from the river's edge.

Recommendations in other sections of this report can also apply to this section on the Ottawa River.

6.2.3 Riverine, Lake

6.2.3.1 Maintaining Wetlands and Pervious Surfaces

Estimates suggest that 68% of the wetlands originally present in southern Ontario were lost by the early 1980s (State of Ontario's Biodiversity Report, 2010). An additional 4% has been lost since this time (State of Ontario's Biodiversity Report, 2015). However, a recent assessment has shown that the rate of loss appears to be decreasing (State of Ontario's Biodiversity Report, 2015). While land conversion is the primary cause of wetland loss in southern Ontario, pollution, invasive species, alteration to natural water levels, and climate change also pose serious threats.

Ontario's Great Lakes coastal wetlands have experienced similar historical losses and degradation over the past 200 years. It is estimated that by 1984, 35% of wetlands along the Canadian shores of Lakes Erie, Ontario and St. Clair had been lost, with the greatest losses occurring between Toronto and the Niagara River. Loss and degradation continue today, largely resulting from shoreline alteration, water level control, nutrient and sediment loading, invasive species, dredging and development. Upstream land use practices also have an impact, particularly through runoff from urban and industrial development, agricultural lands and impervious surfaces. Despite some localized loss and degradation, wetlands in the northern part of Ontario (Hudson Bay Lowlands and Ontario Shield ecozones) remain largely intact.

Wetlands act as natural stormwater management ponds, slowing the speed of flood waters and storing large quantities of surface water. Maintaining, restoring or constructing wetlands can be a cost-effective way of reducing flood risks and associated costs. A study commissioned in part by the MNRF in 2017 found that maintaining wetlands can reduce flood damages and costs by 29% in rural areas and by 38% in urban areas. The Insurance Bureau of Canada (IBC) has also recently issued a report documenting the ability of wetlands to reduce flood damages, and promoting wetlands and other natural infrastructure as "a viable alternative to grey infrastructure option[s] for flood mitigation" and "a cost-effective way to mitigate material financial losses that would otherwise result from flooding." (Combatting Canada's Rising Flood Costs, September, 2018: <http://assets.ibc.ca/Documents/Resources/IBC-Natural-Infrastructure-Report-2018.pdf>).

Recommendation #17

That the Province support municipalities and conservation authorities to ensure the conservation, restoration and creation of natural green infrastructure (i.e. wetlands, forest cover, pervious surfaces) during land use planning to reduce runoff and mitigate the impacts of flooding.

6.2.3.2 North Bay/Mattawa Area

As discussed in Section 4.2, there are two distinct watersheds in the MNRF North Bay District—the Sturgeon-Nipissing-French and the Upper Ottawa River. In the engagement session, it was quite apparent from representatives from both areas, that each area had their own distinct experience through the spring freshet.

In general, there was much more collaboration between all interested parties in the Sturgeon-Nipissing-French area, and although difficult decisions needed to be made regarding what area would see more water and when, at the end of the day everyone had the opportunity for input, everyone was well informed of the situations in the entire watershed, and everyone signed off on the final decisions. This resulted in a successful outcome in the sense that they did the best they possibly could in a bad situation.

Recommendation #18

That the MNRF North Bay District facilitate a meeting between the Sturgeon-Nipissing-French watershed group and the Upper Ottawa River Watershed group to help the latter group establish a collaborative arrangement for future flood events. It is important that all parties involved in the flood be present at the meeting.

Also as discussed in Section 4.2, the City of North Bay undertook a contingency plan to protect the wastewater treatment plant. However, if Lake Nipissing had reached a critical elevation, the wastewater treatment capabilities would have been severely limited, and there was no ability to bypass the plant and temporarily discharge (during the extreme flood event scenario) directly to the lake, which meant that a huge area of the City of North Bay would experience sewer backup and a few thousand residents would have needed to be evacuated.

Recommendation #19

That the City of North Bay in particular, and any other municipalities in a similar situation, install appropriate treatment plant bypass piping to improve resiliency of key infrastructure and limit the impacts of flooding on this infrastructure and associated impacts to public health and safety.

Based on their experience with the 2019 flood, but also events in previous years, the North Bay/Mattawa session participants suggested that the Lake Nipissing operational guidelines be reviewed.

Recommendation #20

That the Province, the federal government (Public Service and Procurement Canada) and the North Bay-Mattawa Conservation Authority review the Lake Nipissing Operational Guidelines.

6.2.3.3 The Muskoka/Magnetawan Rivers/Lakes

The Muskoka and Magnetawan Rivers are both complex systems with many factors impacting water levels, including physical geography, rainfall, snowpack and temperatures. They are both cascading systems and both originate on the western slopes of Algonquin Provincial Park. Dam operations are guided by the Muskoka Water Management Plan and Dam Operations Manual, and the Magnetawan Dam Operations Manual. There are no conservation authorities in either watershed, meaning the MNRF Parry Sound District Office and other dam owners are responsible for water management operations.

The public and residents have high expectations that the dam operations will maintain relatively static water levels and prevent floods. However, the dams are not flood control structures and have very limited capacity to store or hold back flood waters, as they have little to no lake or reservoir capacity. As a result, in a large volume, rapid runoff flood, the dams have limited capacity to reduce peak water levels. The greater the flood event, the less ability the MNRF/dam operators have to mitigate the impacts.

The dams were originally constructed to facilitate the transport of logs to sawmills and aid in commercial navigation. Over time, the operational emphasis has evolved from commerce and transportation to the provision of a balance of social/recreational, environmental and economic interests. To meet these interests, and to the extent possible, the MNRF operates the dams to maintain water levels within ranges identified in the established dam operating plan. These plans were formalized in the Water

Management Plans, and are based on normal conditions. The general public and stakeholders have been critical of how the dams are operated, not only with high water conditions but low water conditions as well.

Recommendation #21

That the MNRF establish a communication protocol to inform and involve key stakeholders (i.e. municipalities) on watershed conditions and operations throughout the fall and winter leading into and throughout the spring freshet, commencing in early 2020.

While there is growing development along the shorelines within the Magnetawan River watershed, there is significant development along the shorelines within the Muskoka River watershed. Accordingly, there is keen interest from local stakeholders and municipalities in the Muskoka River Water Management Plan.

In August 2018, the Province announced a \$5 million Muskoka Watershed Conservation and Management Initiative to better identify risks and issues facing the Muskoka Region. The government also committed to matching tax-deductible donations up to an additional \$5 million. By protecting this particular watershed and working with the local community, this initiative will help the Province develop a comprehensive approach to watershed management, which can inform current actions and future development.

On August 7, 2019, the Minister of Environment, Conservation and Parks announced the appointment of nine members to the Muskoka Watershed Advisory Group. The Advisory Group is tasked with providing advice and recommendations to the Minister on measures to protect the health of the watershed and support the economic growth in the region. An effective watershed management approach is important to the residents of the Muskoka, especially as the watershed faces pressures and stresses from increased development, increasing contaminants and nutrient loads, and intense and frequent flooding caused by extreme weather events.

Recommendation #22

That the Ministry of Environment, Conservation and Parks (MECP) use the results of the Muskoka Watershed Conservation and Management Initiative to inform any potential future amendments to the Muskoka River Water Management Plan by working with the Ministry of Natural Resources and Forestry, and in the meantime, that the MECP consider whether to encourage the municipalities to establish a conservation authority or request the Ministry of Municipal Affairs and Housing to restrict development in the floodplains (e.g. Ministerial Order).

6.2.3.4 County of Haliburton/Trent Severn Waterway

Haliburton County is a large geographic area with multiple municipalities and infrastructure jurisdictions, including the Trent Severn Waterway (Parks Canada), the Province of Ontario (Ministry of Transportation, MNRF), the Crowe Valley Conservation Authority, the County of Haliburton, and the four local municipalities of Algonquin Highlands (Dysart et al, Highlands East and Minden Hills). This situation is somewhat unique with the number of watersheds and federal dams.

Six watersheds are represented in Haliburton County, but the majority of the County is located outside the jurisdiction of a conservation authority. The municipality of Highlands East is located within the jurisdiction of the Crowe Valley Conservation Authority.

Water originating in Haliburton County supplies water to the Trent Severn Canal but also for 47 downstream drinking water systems for communities such as Bobcaygeon Fenelon Falls, Lindsay, Peterborough and Trenton. There are 28 Trent-Severn Waterway (TSW) controlled dams above the village of Minden and the agency leads its own processes associated with dam operations and water level management. During high water conditions and flooding, TSW convenes conference calls to advise the MNRF and conservation authorities of current and predicted short-term dam operations strategies. Within the area, the MNRF operates four dams with specific operation plans, but these are operated in conjunction and collaboration with TSW operations.

As a result of the Haliburton County experiences with flooding over the last few years, there are now regular “spring freshet” conference calls held by staff of the MNRF and Trent-Severn Waterway, along with elected officials and administrative officials from emergency services, public works, etc. This collaboration has been reported as a success for helping disseminate information to the front-line people working to combat the flooding impacts, including municipal staff, conservation authority staff and the public.

A collaborative agency called the Upper Trent Water Management Partnership (UTWMP) was formed among the municipalities of Algonquin Highlands, Dysart et al, Minden Hills, Highlands East, North Kawartha, Trent Lakes, and the Coalition for Equitable Water Flow. The mission of UTWMP is to speak as a single voice for all stakeholders on water management issues affecting the reservoir and flow-through lakes, and to provide local water management leadership.

The County has partnered with Trent Severn Waterway, Kawartha Region Conservation Authority, Ganaraska Region Conservation Authority, and the Upper Trent Water Management Partnership to form a steering committee to oversee the completion of LiDAR, hydrology and mapping.

The County was successful in receiving National Disaster Mitigation Program (NDMP) funding for airborne LiDAR survey data for the Burnt and Gull River Watersheds; however, additional funding to complete data analysis, hydrologic and hydraulic models and floodplain maps was denied as this work wouldn't be complete before the program end date of March 2020. It is the intent of the County to apply for funding to complete this work if the program is extended.

Recommendation #23

That Haliburton County document how their collaborative model worked for the 2019 flood and share this information with, and for the benefit of, other counties, municipalities and conservation authorities.

6.2.3.5 Southwestern Ontario

As mentioned in Section 6.2.1 above, the shorelines of the Great Lakes and the St. Lawrence River have and continue to be significantly impacted by very high lake levels and erosion. The focus in that section is mainly on mitigation methods using typical infrastructure solutions and associated funding mechanisms. However, municipalities are looking for bigger picture solutions as they acknowledge that these are not affordable.

The municipalities and conservation authorities in southwestern Ontario held a Roundtable Information meeting on September 19, 2019, in London, Ontario. The meeting was attended (in person or by phone) by municipalities (Chatham-Kent, Leamington, Windsor, Essex, Kingsville, Tecumseh, Pelee Island, Amherstburg, LaSalle, Elgin), conservation authorities (Lower Thames, Essex Region, St. Clair Region, and Kettle Creek), provincial departments, federal departments, the Great

Lakes St. Lawrence Collaborative and Zuzek, Inc. (consultant). A summary from the meeting resulted in the following statements:

High water levels and floods of 2019 must be viewed as a warning/wake up call. Change is needed – maintaining the status quo in policy and practice cannot continue. Municipalities cannot afford the infrastructure problems our current development approach creates, let alone future costs associated with climate change. There is an opportunity for the Provincial Government to work with Conservation Authorities and the Federal Government to lead a revolution on shoreline management. The shorelines, the ecosystems they support, the biodiversity, and ecosystem goods and services are simply too valuable to treat them like undeveloped subdivisions.

The Roundtable also resulted in a number of recommendations, some of which have been captured in other areas of this report, but I am highlighting one here:

Recommendation #24

That the provincial, federal and municipal governments work with the Essex Region Conservation Authority and the Lower Thames Valley Conservation Authority to undertake a coordinated short- and long-term strategy to address the existing and expected impacts to Chatham-Kent, Windsor-Essex and Pelee Island as a result of current and future water levels, flood and erosion hazards, and climate change on Lake Erie, Lake St. Clair and the Detroit River.

6.2.3.6 Flood Protection Land Forms

Some municipalities are considering the use of “flood protection landforms” to open hazardous areas up to new or intensified development. This is the approach currently being taken by the City of Toronto to open lands east of the Don River to development—a \$1.25 billion development project supported by all three levels of government. The approach taken was permitted as a “one-off” and represents a considerable deviation from the MNR’s natural hazard technical guides and the Provincial Policy Statement, as documented in a protocol signed by the City of Toronto, the Ministry of Municipal Affairs and Housing and the MNR.

Existing ministry policies do not support using flood protection landforms to open new areas for development. Specifically, the MNR’s Technical Guide – River and Stream Systems: Flooding Hazard Limit (2002) does not support the use of flood protection landforms (e.g. berms, dikes, flood walls, and other such structural methods) as permanent flood control structures or to facilitate development in hazardous areas.

Flood protection landforms can result in increases in upstream flood levels, increases in downstream flows and increases in downstream velocities. The construction of flood protection landforms can create new or aggravate existing hazards and would therefore not be consistent with Section 3.0 of the Provincial Policy Statement. Flood protection landforms and other structural measures can be overtopped making flooding worse, and they often inspire a false sense of security thereby encouraging further development in hazardous areas. Structural measures are associated with high costs, during construction and in perpetuity afterwards. Inspection, certification, maintenance, operation and repair are ongoing, often unaffordable for local communities. New construction adds to the existing municipal infrastructure deficit.

Increasing development pressures and high-profile projects, such as the Lower Don Development project, is forcing the Ministry to defend its current approach to hazard management and how best to balance the use of prevention versus protection to manage flooding and other natural hazards.

While prevention-based approaches have been repeatedly shown to be more effective in reducing the impacts of flooding and other natural hazards, flood protection landforms do have a role to play in certain situations, and the approach taken to develop the lower Don area is an excellent example. The value of the proposed real estate development has justified the great expense of ensuring that all the issues and concerns of a permanent landform and the intense development behind it in the floodplain were appropriately dealt with, including being adaptive to climate change by building higher than the design flood. While flooding will always be potentially a risk, the risk has been reduced.

There is a strong possibility that the protocol for the lower Don area and the City of Toronto's flood protection infrastructure projects will set a precedent for other areas in the province. To ensure that developers, municipalities and conservation authorities adhere to strict requirements and conditions to permit such a development in the hazard lands, this new category, the requirements and conditions should all be enshrined in legislation (regulation).

Recommendation #25

That the MNRF review and update the appropriate technical guides, with consideration of a new category permitting development in hazardous lands along large inland lakes, rivers and streams, and along the Great Lakes/St. Lawrence River, utilizing flood protection land forms and/or other forms of flood protection and floodproofing methods with very strict requirements and conditions. Further, consideration should be given to enshrining this concept in legislation or in a regulation along with other structural methods that are now permitted in non-hazard lands or Special Policy Areas.

6.2.4 Urban/Flash Flooding (Pluvial Flooding)

There are many examples of pluvial flooding in urban areas that have resulted in major disruptions of service and significant impacts on property, businesses, homes and people.

This type of flooding occurs during heavy rainfall events independent of an overflowing river or stream. The ground cannot absorb the water as quickly as it falls, especially in urban areas with a lot of hard surfaces like pavement. Drainage systems (such as human-made and natural channels, roadways, storm and combined sewers) can quickly become overwhelmed, causing water to pond in parking lots, flow into streets and nearby homes and structures, or back up into basements.

Floodplain mapping is not really practical, as overland and sewer flooding can occur anywhere in the urban area. This is partly because of the spatial variability of the “eye” of the rainstorm, but also due to the local topography, unique development (legacy and new), and the type of drainage systems in each neighborhood.

Challenges with pluvial flooding include increased imperviousness over time; inadequate surface drainage plan; private property being lower than the streets (either the grade at the house or reverse slope driveways); reliance on storm sewers that are designed for smaller rainstorm events; sedimentation of channels and sewers; blocked culverts or curb inlets; inflow and infiltration; sewer and channel design capacity limitations in older neighborhoods; deteriorated sewers; reduced sewer or wastewater treatment plant capacity due to high water levels in the receiving stream (and lack of proper gates); and failures of pumping stations or wastewater treatment plants.

There is a substantial difference between managing floods in newer greenfield development and historically developed areas, and some of the latter areas are subject to intensification or infill development pressures. In the greenfield areas, non-structural

and structural mitigation methods, including green infrastructure, can be incorporated as part of the development. In older areas, municipalities are faced with significant costs to rehabilitate, enhance or build new flood protection infrastructure for drainage systems. There are also challenges for municipalities when a newer greenfield development must utilize an existing drainage system downstream through an existing development.

Stormwater management in Canada has been evolving over the years, and system components are not only dealing with the quantity of stormwater but the quality as well (pollution reduction and erosion protection). Installation of regional stormwater management (retention or detention) ponds or linear naturalized channels has achieved both objectives, although quality improvement to a lesser degree.

6.2.4.1 Use of Regional Flood Control Facilities

Development practices are also changing and exposing potential regulatory gaps.

Stormwater management facilities are regulated in Ontario by the Ministry of Environment, Conservation and Parks (MECP). Under the *Environmental Protection Act*, an approval is issued for the purpose of stormwater management works to provide for an enhanced level of water quality control, erosion protection, and attenuation of post-development storm flows up to and including the 100-year storm event. Regional Flood Control Facilities (RFCFs) are increasingly being constructed in some areas to help mitigate flooding in urban areas. RFCFs are stormwater management ponds that are designed to control flooding associated with much larger regional storm events (e.g. Hurricane Hazel for GTA communities) exceeding the 1% storm and well above and beyond the capacity of traditional stormwater management (SWM) ponds.

While traditional SWM ponds are considered to pose a relatively low risk to downstream landowners, the risks associated with the increased use of RFCFs are largely unknown, and they are not regulated by the MNR. RFCFs retain significant volumes of stormwater runoff and could cause significant flood damages if they were to fail, raising concerns that the use of these facilities creates new, or aggravates existing, flood hazards, particularly when built immediately upstream of residential areas.

Due to their design, RFCFs function more like dams than traditional SWM ponds (i.e. they provide flood control function). Unlike dams, there are no provincially approved structural design standards for RFCFs.

The construction of these structures can be viewed as creating new hazards and thereby conflicting with provincial policy direction which states that “planning for stormwater management shall not increase the risks to human health and safety and property damage.” In addition, the MNR’s Technical Guide specifies that stormwater

management facilities are not to be used to provide any reduction in flood flows, and accounting for their storage in flood hazard mapping artificially reduces the extent of regulatory flood lines and is non-compliant with the MNRFs Technical Guide.

While many of these RFCFs are being constructed to support greenfield development, they are also being used in existing developments, often in highly urbanized landscapes. In some instances, RFCFs are being constructed for the purpose reducing flood flows and freeing up flood hazard lands for intensified development by artificially reducing the size of floodplains (i.e. redrawing flood lines) downstream of RFCFs, through amendments to existing flood hazard maps (i.e. floodplain maps) used to guide land use planning decisions. The MNRF views this as putting people and property in harm's way and contrary to the MNRF's Technical Guide and the Provincial Policy Statement (PPS).

While the construction of these structures has been limited, they are becoming more common (more than 50 of these structures within 46 Ontario communities) as determined by a study commissioned by the MNRF. Apparently, many of them are being built larger than their original design specifications with the aim of holding back even larger volumes of water. A prevalent perception observed when collecting data for the study was that RFCFs protect downstream landowners and these larger ponds contribute to safety rather than increased risk. The study documented that one-third of the RFCFs examined represented an increased risk to downstream communities in the event of a failure. Furthermore, the risks and consequences of failure of these facilities is not typically a design consideration. Important factors determining risk of RFCFs included the size of the pond and the embankment height, with the most influential factor in determining the risks of these facilities being the pond configuration and landscape setting (e.g. elevation of pond relative to downstream receptors) specifically in relation to populated areas.

Recommendation #26

That, due to the increased use of the regional flood control facilities, the MNRF review whether the Province should take steps to regulate the use of these structures or let municipalities decide their use.

The above issue raises the point that there is a lack of clarity around the MNRF's role in urban flooding. To date, the MNRF's focus has been on flooding from waterbodies (rivers, streams and lakes), suggesting that "urban flooding"—owing to its linkage with stormwater management and development infrastructure—should be borne by ministries with mandates related to those components (i.e. MECP, MOI, MMAH, etc.).

Recommendation #27

That the Province create a working group of all pertinent ministries to define their respective roles as they pertain to pluvial flooding.

6.2.4.2 Municipal By-laws – Pre-development Rates of Runoff

One of the methods to reduce the impact of intense rainstorm events on drainage systems is to limit new development to “pre-development” rates of stormwater runoff. All the new hard surface means that rain or snowmelt water will runoff at a much greater rate than previous agricultural use or natural habitat. By limiting the runoff to the pre-development rate, the drainage system downstream will see no more water after development than before development.

For a new subdivision, restricting to pre-development rates may be achieved with a combination of conventional stormwater management techniques (i.e. dry or wet pond) and other low impact development practices. For multi-residential or commercial situations, such as a high-rise tower or shopping mall, detention of the stormwater can be achieved by on-site storage (roof-top, underground tank, open retention basin or parking lot storage) and/or by using permeable surfaces.

6.2.4.3 Municipal By-laws – Flood Protection Measures for Private Property

Flood protection of private property is not just a municipal responsibility but also a property owner responsibility. We put locks on our doors because we can't expect that the police service will protect our houses from intruders. Neither can we expect that the drainage system will protect us from all storm events. Accordingly, residents and other property owners have a responsibility to protect from pluvial flooding by the installation of backwater valves, sump pits and pumps, sealing doors and windows, disconnecting downspouts from the sanitary sewer, and building up the earth around the foundation and window wells, etc.

Recommendation #28

That the Province consider whether it should take steps to regulate drainage standards in urban areas, such as the requirement to restrict runoff flows to pre-development rates and flood protection measures for private property, and if so, what is the most appropriate legislation.

6.2.4.4 Intact Centre on Climate Adaptation

The Intact Centre on Climate Adaptation (Intact Centre) is an applied research centre with a national focus located within the Faculty of Environment at the University of Waterloo. The Intact Centre was founded with a gift from the Intact Financial Corporation. The Intact Centre works with homeowners, communities, governments and businesses to identify the impacts of extreme weather and climate change, and to develop the practical tools needed to help communities adapt to these changes and minimize impacts.

A particular focus of the Intact Centre over the last three years has been the development and testing of a variety of tools that have advanced flood risk reduction in Canada. From 2016 to 2018, the Intact Centre’s Home Flood Protection Program developed a home flood risk assessment tool and assessor training program, and delivered over 500 flood risk assessments to residents in Ontario and Saskatchewan. Learnings from the program delivery contributed to the publication of a national guideline for basement flooding protection (CSA Z800-18) in 2018. Additionally, in April 2019, a report titled: “Water on the Rise: Protecting Canadian Homes from the Growing Threat of Flooding” was released by the Intact Centre summarizing the top flood risks associated with residential homes and the best practices for motivating action in order to reduce risk.

The Intact Centre is committed to working with municipal and provincial governments to educate residents. The Intact Centre has also published several other reports on flooding, all of which can be found on their website (<https://www.intactcentreclimateadaptation.ca>).

Recommendation #29

That the Ministry of Environment, Conservation and Parks reach out to the Intact Centre for Climate Adaptation, as part of their commitment to consult with the insurance and real estate industry under the 2018 Environment Plan, to work collaboratively to raise awareness among homeowners about the increasing risk of flooding and to disseminate the basement flooding protection information to homeowners.

6.2.5 Funding for Permanent Works

Following significant events, there is always a demand for funding for more permanent works (infrastructure such as a dam, bridge, shoreline protection work, erosion control infrastructure, etc. that will be designed, used and remain in place over the long term)

by local officials and the general public. Given the financial pressures that governments are facing currently, a potential immediate source would be existing programs, such as the Ontario Community Infrastructure Fund (OCIF) program, the Federal Investing in Canada Infrastructure Program (ICIP), the Ontario Water Erosion Control Infrastructure (WECI) program, and the Ontario Financing Authority green bond program.

Recommendation #30

That the Ministry of Infrastructure ensure that the Ontario Community Infrastructure Fund supports municipalities in enhancing and implementing asset management plans (which includes stormwater management and consideration of climate change adaptation and mitigation activities), which will help municipalities make the best possible investment decisions for their infrastructure assets.

Recommendation #31

That the Ministry of Infrastructure work specifically with the MNRF on the design of future intakes of the Green stream of the Investing in Canada Infrastructure Program to ensure flood-related projects are eligible.

The Province's Water Erosion Control Infrastructure (WECI) program is an effective provincial-municipal cost-share program for maintenance of water control infrastructure that reduces flooding, mitigates flood damages and disruption to the economy. Currently, the program is funded through the MNRF capital program budget on a fiscal year basis, and it is suggested that a multi-year budget be established for some larger maintenance projects that may span many years to provide flexibility for future potential fluctuations in funding requests.

Recommendation #32

That the Province continue to fund the Water Erosion Control Infrastructure program and consider adopting a multi-year budget.

The Ontario Financing Authority runs a green bond program that includes five categories— Clean Transportation; Energy Efficiency and Conservation; Clean Energy and Technology; Forestry, Agriculture and Land Management; and Climate Adaption and Resilience. Under the last category, the following projects will generally be considered eligible—flood protection and stormwater management; extreme weather resistant infrastructure and municipal infrastructure for clean and/or drinking water;

wastewater treatment; sustainable urban drainage systems; and other forms of flooding mitigation. (See more details at www.ofina.on.ca/greenbonds.)

Recommendation #33

That the Province continue to issue Green Bonds in 2020 and beyond to help finance extreme-weather resistant infrastructure.

6.3 Preparedness

6.3.1 Monitoring and Data Management

6.3.1.1 The Hydrometric Agreement

There is always an argument for better hydrometric data; however, the fiscal realities likely mean that there will be no significant increase in funding for the hydrometric network.

Recommendation #34

That the Province continue its financial commitment and partnership arrangement with the federal government through the hydrometric network agreement.

Recommendation #35

That the Province continue to monitor the effectiveness and location of gauges to ensure that there is appropriate coverage and consider repositioning gauges if necessary.

Recommendation #36

That, where appropriate and where funding permits, the Province consider the installation of GOES telemetry at key locations where more frequent access to information is required (areas of higher risk/watersheds that react quickly to changes in precipitation or snowmelt) and where current landline telecommunication technology is less secure and not as reliable in transmitting information.

Recommendation #37

That, where appropriate and where funding permits, the Province consider the use of automated alarms at those stations in watersheds of higher risk/quick response to precipitation and snowmelt to alert when water levels have exceeded a threshold of concern.

6.3.1.2 Climate (Weather) Monitoring

While there is heavy reliance on the hydrometric network, it is recognized that weather “inputs” are critical to understanding and predicting events. Citizen science is an effective tool in gaining additional precipitation information (such as through the Community Collaborative Rain, Hail and Snow Network or CoCoRAHS), typically at a lower cost and at low risk.

Recommendation #38

That the Province explore whether there would be value toward additional manual snow course locations in those watersheds where snow cover and snow water content are factors in spring flooding, and seek to involve the citizens in the collection and reporting of that data.

Recommendation #39

That the Province explore the feasibility of remote sensing products to better estimate the spatial distribution of snow and snow patterns.

6.3.1.3 Data Management

Beyond the MNRF, there are a number of other organizations or agencies that collect or have data that would be beneficial toward enhancing flood forecasting.

Recommendation #40

That the MNRF work with federal, provincial and local partners as well as industry toward an Open Data model where information is shared and consolidated into the existing Surface Water Monitoring Centre (SWMC) hydrometric monitoring database.

6.3.1.4 Satellite Remote Sensing

Although currently operationally working in an emergency management environment, the MNRF's Remote Sensing Science Group is not an emergency management tasked group. The recent launch of the three RADARSAT Constellation Mission satellites highlights a significant opportunity to improve flood and ice monitoring, but will require additional provincial resources to coordinate, process, interpret and disseminate information in near real time. The portfolio of satellite imagery products and services the Remote Sensing Science Group supports to aid the emergency management products and services is growing year upon year.

Currently the Remote Sensing group supports emergency management flood monitoring only during the spring flooding season.

Additional remote sensing satellite monitoring opportunities (e.g. snow extent and snow water equivalent) remain unexplored/unexploited provincially due to resourcing.

Recommendation #41

That the Province investigate the return on investment of utilizing the new satellite imagery and resourcing with the necessary staff additions to provide better flood forecasting and monitoring.

6.3.2 Flood Forecasting and Warning

Flood forecasting and warning plays an important role in achieving the provincial objective of reducing risk to life and reducing property damages. It is particularly important to residents located in a floodplain where permanent mitigation works do not exist. The flood forecasting and warning system is very reliant on the provincial hydrometric network (stream gauges), from which the data is used to make decisions of when to issue flood warnings, operate infrastructure (such as dams), and provide real-time status reports on flooding on different reaches of a river. The stream gauge networks also provide an important history of flooding.

Flood forecasting and warning requires integration with municipal emergency response. However, there is inconsistent resourcing for flood forecasting and warning across the province. Conservation authorities are not present in all areas of the province. In areas without conservation authorities, flood forecasting and warning is the responsibility of the local MNRF district office. Not all conservation authorities and districts are consistently equipped or resourced in order to provide flood forecasting and warning services.

Updated floodplain mapping provides the opportunity to produce new products to aid in flood forecasting and warning, and emergency response. Floodplain maps can provide a fundamental base for designing and developing response plans for a range of floods. Updated hydrology modelling for floodplain mapping can be leveraged to create new up-to-date flood forecasting models. Flood forecasting and warning systems can be designed to reflect the local watershed characteristics and be risk-based. More sophisticated complex warning systems can be implemented where the risk is highest, and less complex systems where there is lower risk and more lead time.

An ideal system would include developing real-time flood forecasting models that merge hourly forecasts with radar and real-time gauge data, the use of machine learning algorithms for data assimilation, and ensemble forecasting for areas where flood vulnerability has been identified. Flood messages should target people within affected geographic areas and consider the use of Common Alerting Protocol – Canadian Profile format. This would increase coordination, interoperability and efficiency between agencies. Over the long term, this could integrate with the Canadian Alert Ready platform and mobile telephone public safety apps.

Recommendation #42

That the Province update the flood forecasting and warning guidelines, providing clarity on roles and responsibilities (conservation authorities, MNRF district offices, municipalities) and provide examples of the systems, from simple to complex, with recognition that each system should be designed to reflect the local watershed characteristics and resources.

6.4 Emergency Response

6.4.1 Emergency Operations

As first discussed above in Section 6.1.4.1, Chapter 3 of the 2017 Auditor General's report raised concerns regarding the current governance structure for emergency management in Ontario.

The Office of the Fire Marshall and Emergency Management (OFMEM) within the Ministry of the Solicitor General, is taking action to address the Auditor General recommendations and other reviews. The following are two additional initiatives planned or currently underway that will improve emergency operations around floods:

- 1) AG recommendation to enhance Emergency Management program capacity – Emergency Management Ontario (EMO) to enhance readiness for large-scale

emergencies; adopt and meet international/national best practices; mandate use of the Incident Management System; and enter into mutual assistance agreements with neighbouring jurisdictions.

- 2) AG recommendation to increase support to municipalities and emergency management partners – EMO to enable the Provincial Emergency Operations Centre (PEOC) to more quickly deploy resources to supplement local capacity; implement emergency management software to support provincial-municipal information and resource sharing; enhance capacity to deploy humanitarian aid; and implement emergency management supply chain/logistics program.

Recommendation #43

That the Ministry of the Solicitor General implement emergency operations initiatives in response to the recommendations of the Auditor General as soon as possible.

During my engagement sessions, I did receive a lot of feedback from municipalities about improvements they would like to see implemented by EMO. In short, once they declare an emergency and request assistance from the Province, they want the Province to be more involved in coordinating a response and ensuring that the municipality has access to the resources and expertise it needs. Municipalities also request that the Province condense their requirements for reporting during an event, as it distracts from the actions needed to fight a flood, including reducing the amount of paperwork and daily reporting during a flood to multiple people at EMO.

Recommendation #44

That Emergency Management Ontario improve its processes for interacting with municipalities and clearly lay out the processes on their website.

Another complaint of municipalities was how the Canadian Forces (CF) were deployed. Municipalities do not understand the process as to how the Province engages the CF, and more importantly what activities the CF are approved to implement. In one municipality, the CF was distributing potable water when the municipality needed their help building sandbag dikes.

However, the focus should be on how the municipalities ask for assistance with specific needs rather than how to ask for a specific group's assistance. The Province should determine best how to support the request and whether it can be done without federal support.

Recommendation #45

That Emergency Management Ontario clearly lay out the process for municipalities to request assistance during emergencies and provide field support to help determine the assistance that is required.

6.4.2 Communications

A better job could be done with communication and information dissemination before, during and after a flood, but most critically during a flood. Municipalities and residents demand good information so they can make informed decisions. Timely information is also key, such as forecast peak water levels, to allow appropriate preparations to be made to protect people and property.

Many smaller municipalities and CAs don't have the resources to hire technical and communications specialists (either full-time or part-time) to answer public inquiries during a flood event. They get questions such as: "Who do I approach to ask for assistance with sandbagging?" or "What is the forecast peak water level at X location?" or "How do I build a sandbag dike?"

Recommendation #46

That the Province have a central website for flooding issues that provides answers (for conservation authorities, municipalities and the public) to a myriad of typical and frequent questions, or at the very least, a link to the agency (provincial department, power company, etc.) that provides the answers to the questions.

6.5 Recovery

6.5.1 Compensation for Damages and Rebuilding

6.5.1.1 Compensation Programs

In many of the municipal engagement sessions, many smaller municipalities advised me that achieving the damage threshold of 3% of their total own purpose taxation (revenue) to be eligible for financial assistance is difficult. Further, if a municipality did not meet the 3% threshold, they were also excluded from the "build back better" pilot.

Recommendation #47

That the Province review the funding formula for eligibility of municipalities under the Municipal Disaster Recovery Assistance program.

As discussed in Section 5.3.2, partly in response to flooding in spring 2019, the Ministry of Municipal Affairs and Housing created a \$1 million pilot project designed to help municipalities repair flood damaged roads, bridges and other infrastructure to a higher standard so they can better withstand extreme weather. As part of a \$1 million pilot project, the province will provide municipalities that qualify for MDRA funding with up to 15% above the estimated cost of rebuilding damaged public infrastructure to make it more resilient to extreme weather. This is a very important program, as the investment to “build back better” will reduce flood damage in future events and therefore provides a return on the investment.

Recommendation #48

That the “build back better” pilot under the Municipal Disaster Recovery Assistance program move from a “pilot” to a full program. The Province should consider raising the 15% cap where it makes economic sense. The program should be tied to legislated flood protection levels and floodproofing criteria. For example, a bridge damaged by a flood can only be replaced if it is raised to the design flood.

There is no “build back better” component under the Disaster Recovery Assistance for Ontarians (DRAO) program. Under that program, assistance is based on the cost of returning a property to a functional level, which includes meeting building code requirements. Eligible costs may include floodproofing as required to obtain a building permit. Under the applicable provisions of the *Building Code Act*, the municipality must not issue a building permit in a regulated flood zone unless the conservation authority (or the MNRF in areas with no CA) has issued the required permit, which would include floodproofing requirements. DRAO does not cover floodproofing that is not required to obtain a building permit.

However, in municipal engagement sessions I heard several stories of individuals who repaired their houses after the 2017 flood only to be flooded again in the 2019 flood, and who claimed that had they been able to “build back better” after the 2017 flood that their damages in 2019 would have been eliminated or reduced. It is not clear if the damages were caused by flooding that exceeded the design flood or designated flood protection level for the area.

Recommendation #49

That the Province consider including a “build back better” component under the Disaster Recovery Assistance for Ontarians program.

At another municipal engagement session, I was advised that a home on leased land on a First Nation reserve and leased by a “non-status” person is not eligible under either the federal or provincial disaster assistance programs. The DRAO does not have any eligibility restrictions on leased land except if it is on First Nation reserve land. Indigenous Services Canada offers disaster assistance programs on First Nation reserves but only “status” residents are eligible. There are two possible ways to address this—the federal government could expand its program to include non-status individuals leasing on reserve land, or the province could expand its program to include reserve land. There would be a number of considerations that would come into play with the latter, including that provincial planning and building regulation policies do not apply on reserve land.

Recommendation #50

That the Province approach Indigenous Services Canada about expanding their disaster assistance program to include houses that are leased on First Nation reserve land by non-status individuals.

6.5.1.2 Relocation and Buyouts

A number of individuals and groups who participated in the review were interested in a buyout program being made available to residents living in floodplains whose homes were severely damaged by the 2019 flood events.

Buyouts can be beneficial when it is anticipated that the cost of more frequent emergency response activities and disaster assistance costs will outweigh the cost of providing those homeowners with fair market value for their homes. Also, buyouts are sometimes necessary when it is not technically feasible to meet floodproofing criteria, although this situation is not common. These programs can be highly contentious depending on how market value is determined and whether these programs are optional or forced onto residents in high-risk areas.

Recommendation #51

That the Disaster Recovery Assistance for Ontarians program be flexible enough to allow for removal of the structure from the floodplain (buyout) if it is the only technically and financially feasible option.

6.5.2 Insurance

Section 5.1.5 discussed that financial assistance for most flooding events in Ontario is largely provided by the Province or costs are borne by the property owner.

The flooding costs borne by property owners in Ontario are due to the limited insurability of flood risk areas. However, insured catastrophic losses in Canada (mostly related to water damage) are significantly increasing. Accordingly, the Insurance Bureau of Canada has been conducting research and producing reports on this issue.

“Overland flood insurance is available from a number of insurance companies active in the Ontario marketplace, however it is not available for high-risk properties, or if it is available, it is prohibitively expensive or available with a limited cap, and as a consequence virtually all high-risk zones remain uninsured or underinsured. Overland flood insurance premiums for high risk flood zones can average over \$10,000, while the average premium for all other perils combined in these areas is in the order of \$1,000.”¹

“The limited insurability of flood risk places the burden for post disaster reconstruction and recovery on homeowners and taxpayers who are funding disaster relief spending from federal and provincial governments.”²

¹ Insurance Bureau of Canada (2019). Options for Managing Flood Costs of Canada’s Highest Risk Residential Properties: A report of the National Working Group on Financial Risk of Flooding. June 2019, <http://assets.ibc.ca/Documents/Studies/IBC-Flood-Options-Paper-EN.pdf>.

² IBC (2015) The financial management of flood risk - An international review: Lessons learned from flood management programs in G8 countries, http://assets.ibc.ca/Documents/Natural%20Disasters/The_Financial_Management_of_Flood_Risk.pdf.

“Currently, for every dollar of insured losses borne by insurers in Canada, three to four dollars are borne by governments and home and business owners.”³

Although the market is now starting to change, residential coverage for overland flooding has historically not been available in Canada on the basis that it lacks economic viability. However, this is starting to change.

“As of spring 2019, 16 insurers offer overland flood products available to approximately 77% of Canadian property owners, with approximately 34% of Canadians having at least some insurance for overland flood risk.”¹

Residential insurance for overland (pluvial and fluvial) flooding started to become available in Canada in 2015. The emergence of private flood insurance represents a significant redistribution of the financial risks associated with flooding. Despite significant costs to governments (who are typically compelled to provide disaster relief to flooded areas), individual private home and business owners also bear significant costs as disaster relief in Ontario is limited and only covers costs for the restoring “essential property” to a basic standard, up to a limit. Insurance will help to pool individual costs across broader society (who in the future will manage their own financial risks through flood insurance). Further on the concept of pooling costs, the Insurance Bureau of Canada recently released a report in June 2019 titled: “Options for Managing Flood Costs of Canada’s Highest Risk Residential Properties” (<http://assets.ibc.ca/Documents/Studies/IBC-Flood-Options-Paper-EN.pdf>) with input from a members of a private-public sector working group on financial management of flood risk. The report focuses on ways to better manage costs of overland flooding for high risk properties across Canada and advances three potential options: 1) Pure Market Solution: risk borne by homeowners; 2) Evolved Status Quo: risk borne by blend of homeowners and governments; and 3) Create a High-Risk Flood Insurance Pool. Option 3, the creation of a high-risk insurance pool for properties otherwise not able to access affordable flood insurance to cover losses and which would include capping or subsidizing premiums, was advanced as a preferred option. Work is continuing on this option; however, it is postulated that this “pool” could be capitalized through a fund

³ IBC, INTACT, etc. (2018). Combatting Canada’s Rising Flood Costs: Natural Infrastructure is an underutilized option, <http://assets.ibc.ca/Documents/Resources/IBC-Natural-Infrastructure-Report-2018.pdf>.

contributed by governments, and then be supported by insurance premiums paid into the pool and levies assessed on all homeowners or municipal rate payers.

There may be opportunities for the Province and the federal government to work with the insurance market to make flood insurance more available to more Ontarians (and Canadians) through increased investments in the identification and management of flood risks. Effective hazard maps are a pre-condition for establishing an effective flood insurance program. The risks associated with offering flood insurance cannot be adequately assessed without accurate, up-to-date mapping.

Recommendation #52

That the Province continue the dialogue with the Insurance Bureau of Canada and the federal government on the steps needed to make flood insurance more available to more Ontarians.

6.5.3 Waste Materials and Landfills

Smaller municipalities raised the issue of how the significant waste materials from a flood can negatively impact the capacity of a local landfill. Used dirty sandbags, flooded contents from a house or cottage (such as furniture, appliances, etc.) and if the house or cottage is destroyed, all the material from the structure's demolition, can quickly use up landfill capacity. These municipalities claim that even if the waste can be accepted at an alternative landfill, it would most likely have to be hauled further away and the costs of hauling were a concern. And finally, municipalities expressed concern over the time period for the permitting process for establishing a new landfill (or expanding an existing landfill), which may exceed the time remaining before an existing landfill has reached capacity.

Disposal costs are in fact eligible costs under the Municipal Disaster Recovery Assistance (MDRA) program, but there has to be an actual cost incurred by the municipality. For example, if the municipality uses a private landfill and pays the tipping fees, those would be eligible. If the municipality does more runs with their garbage trucks, the overtime costs and additional fuel costs, etc., would be eligible. However, the MDRA is oriented to actual paid expenditures, meaning if a municipality has their own small landfill, there is nothing in the MDRA program to compensate them for the "room" or capacity of the landfill that is used up from flood-related waste materials and reduces the future lifespan of the landfill site, because there is no "out-of-pocket" cost incurred.

Recommendation #53

That the Province ensure that municipalities have all the information regarding eligible items under the Municipal Disaster Recovery Assistance program, including costs for disposal of waste materials from a flood.

Recommendation #54

That the Province consider special or expedited approvals for new or expanded landfills if significant capacity is used up from the disposal of flood-related waste materials.

Chapter 7

Recommendations to External Agencies

Implementation of the following recommendations are focused on agencies outside the jurisdiction or control of the Ministry of Natural Resources and Forestry (MNR). In those cases, I would expect that the MNR can initiate discussions with the particular agency to try and seek agreement for implementation of a recommendation, in full or in part.

All three agencies below provided me with a considerable amount of material either in written form or in PowerPoint presentations, including very descriptive pictures, graphs and charts, during the review. A lot of the information is technical, but goes into considerable detail about their operations before, during and after the flood, including decisions that were made. Some of this information has already been presented to citizens in public meetings.

Recommendation #55

That the International Joint Commission, the Ottawa River Regulation Planning Board, and Ontario Power Generation make their detailed information about their flood operations readily available on their respective websites.

7.1 International Joint Commission

Part of the general public and some stakeholder groups seem to misunderstand how the structures on the St. Lawrence River work and what effect the operation of those structures has during extreme floods. In particular, some believe that the International Joint Commission's (IJC) operation of the structures has a negative impact on Lake Ontario or even Ottawa River flooding. However, it is important to understand that while the IJC's responsibilities include the regulation of outflows at the Moses-Saunders Dam on the St. Lawrence River, they cannot fully regulate the water levels of Lake Ontario and the St. Lawrence River, and they have absolutely no bearing on flows of the Ottawa River. The Moses-Saunders Dam can allow for a higher outflow of waters from Lake Ontario to the St. Lawrence River than the natural conditions before its construction, and the 2017 and 2019 flood peaks on Lake Ontario were lower than those that would have occurred under natural conditions (refer to IJC's website at www.ijc.org for more information).

The IJC has a tremendous amount of good information on their website, but unless you know what you are looking for, it is hard to navigate and you can spend a lot of time

searching through reports to find specific information. The general public should have easy direct access to current issues such as the floods of 2017 and 2019. Having a “2017 Flood” button on the main webpage with links to related reports would be helpful, but illustrations on the Great Lakes -St. Lawrence River system or how the operation of their structures impacted water levels in 2017 should be pulled out of the reports and be prominent on the “2017 Flood” page. For example, Figures 2-1 and 2-2 of the IJC report titled: “Summary of 2017 Great Lakes Basin Conditions and Water Level Impacts to Support Ongoing Regulation Plan Evaluation,” November 13, 2018 (https://ijc.org/sites/default/files/2018-11/GLAM_2017_MainReport_FINAL-20181129_2.pdf), are excellent illustrations of the Great Lakes St. Lawrence River system. Figure 2.6 of the IJC report titled: “Observed Conditions and Regulated Outflows in 2017,” May 25, 2018 (https://ijc.org/sites/default/files/2018-08/ILOSLRB_FloodReport2017.pdf) is an excellent illustration of the water surface profile of Lake Ontario and the St. Lawrence River showing the effects that a release of water needed to achieve a one centimetre drop over a period of one week on Lake Ontario would have on water levels at critical areas of the St. Lawrence River, such as Montreal. There are probably many other illustrations that could be pulled from the reports and prominently displayed.

Recommendation #56

That the International Joint Commission consider meeting with interested stakeholder groups and individuals to explain in considerable detail how their structures are operated.

Recommendation #57

That the International Joint Commission consider creating specific “2017 Flood” and “2019 Flood” buttons for their home webpage and populating those pages with detailed information on the floods and their operations, as well as providing direct links to related reports.

7.2 Ottawa River Regulation Planning Board

Likewise, with the Ottawa River Regulation Planning Board (ORRPB), the general public and stakeholder groups misunderstand how water control structures on the Ottawa River are operated and what effect the operation of those structures has during extreme floods. A common complaint was that the information was too technical for the general public. As a result of the flooding damages in 2017 and 2019, residents

questioned whether more can be done to better plan for and reduce the impacts of flooding in the future.

On July 11, 2019, the Hon. John Yakabuski, Minister of Natural Resources and Forestry, sent a letter to his provincial and federal counterparts requesting their support in conducting an independent review of how the Ottawa River system is managed. The letter requested each counterpart to name an individual within their respective ministries that the MNRF could work with to set out the specific details of the review.

The ORRPB suggested that it may be time to review the actual 1983 Agreement that governs the Board and their roles and responsibilities to determine if the conclusions from 1980 still hold true almost 40 years later. The review could repeat the original process of studying the coordination between generation station operators and exploring reservoir expansion and related costs.

Recommendation #58

That the supporting agencies of the Ottawa River Regulation Planning Board (Canada, Ontario, Quebec and the dam operators) consider reviewing the original agreement, recommendations and guiding principles, and board policies given they are almost 40 years old.

Recommendation #59

That the supporting agencies of the Ottawa River Regulation Planning Board (Canada, Ontario, Quebec and the dam operators) consider removing “Regulation” from the title, as it implies that the Board can actually manage large floods when, in fact, they cannot because of the limited storage capacity of the generating station reservoirs, which were designed for electric power generation and not flood control.

Recommendation #60

That a communications officer be assigned to the Ottawa River Regulation Planning Board to help with messaging during flood events or any public meetings and free up the staff engineers to concentrate on their duties. At least two communications officers should be assigned as needed and well trained in the technical operations. The officers should be from another government department as opposed to Ontario Power Generation or another non-government dam owner, since the public believes the dam owners only care about generating electricity.

Recommendation #61

That a communications person with marketing experience work with the Ottawa River Regulation Planning Board to prepare more easily understood materials for publication. The approach to managing the Ottawa River by the Board is not well understood by the public or government officials. Also, the materials should not be confusing. In one example I saw, a line graph showed a water level difference of 1.0 metres but the text below it stated "> 50 cm or 20 in.

Hydrological forecasts should include better information about water levels all along the Ottawa River. People rarely care about flows, but they want to know what level the river will rise to, so they can prepare accordingly. Most of the information is right at or near a hydro structure, but there are a lot of houses and cottages along the river in between the gauges. Since this is a complicated river, it is recognised that it is difficult to interpolate between two gauges (it's not a straight-line relationship).

Recommendation #62

That the Ottawa River Regulation Planning Board work with Ontario Power Generation and consider installing staff gauges at critical settled locations along the river, and engage residents to read and report on these gauges. These residents have a vested interest in getting accurate information and so their "buy-in" could be to volunteer their time to provide the data.

Recommendation #63

That two municipal officials, one from the Association of Municipalities of Ontario and one from the Quebec counterpart, sit on the Ottawa River Regulation Planning Board. The intent is to provide contact persons on the Board trusted by municipalities in both provinces, and for the municipal representatives on the Board to help disseminate correct and accurate information back to municipalities. Consideration could also be given to adding municipal representatives to the Ottawa River Regulating Committee, in addition to or instead of the Board. It is recognized that the three signatories to the Agreement (Canada, Ontario and Quebec) would have to agree to amending the Agreement for this purpose.

7.3 Ontario Power Generation

As with the above two agencies, the general public and stakeholder groups do not understand how the Ontario Power Generation (OPG) stations work and what effect the operation of those power generating structures has during extreme floods. I included considerable discussion and explanation on the issues that were raised by stakeholders about the Ottawa River in Section 4.1.

Further to that, I must emphasize that while Ontario has many different waterpower producers operating throughout the province, my focus on OPG has been in relation to their operations on the Ottawa River, as they are the only Ontario-based waterpower provider operating on the Ottawa River proper. The recommendations below may also be relevant to other waterpower producers operating throughout Ontario.

Regarding Section 4.1.5, Explanation of Conditions at Des Joachims and the Dry Section at Deux-Rivieres, OPG had originally provided me with two diagrams showing operating levels during normal and high flow conditions to try and illustrate the situation. However, I did not include the diagrams in this report, as I think they would confuse the reader. What would greatly assist the reader would be additional illustrations of how the river goes through the changes from normal to high and back to normal conditions.

Recommendation #64

That Ontario Power Generation create a dynamic illustration regarding the dry section at Deux-Rivieres that “walks” the observer through the changes in water levels during low to normal to high flows, with voice-over explanation of water level changes, and that this video be included on their website.

I also discussed the issues in the upper Ottawa River watershed (Mattawa) in Section 4.2 and recommended a more collaborative approach with better communication in Section 6.2.3.2, which OPG supports.

OPG has made several recommendations to me on other matters and most are covered in other sections of this report.

One operational recommendation that OPG has raised that could reduce flooding impact would be a change of the reservoir refill date in the Water Management Plans for each power dam. It is suggested that the refill date be flexible depending on the watershed conditions, such as size and speed of the freshet in the region. Water Management Plans were not designed to manage floods. Balancing the constraints of the plan with the potential for flooding can sometimes be challenging. The Victoria Day refill constraints have been set primarily for recreational purposes; however, they cause

water management staff to make a trade-off between flood resilience and recreation. The refill date should not be based on a set trigger (or series of potential triggers), but allowed to be based on the unique conditions of each given year.

Recommendation #65

That Ontario Power Generation identify options to address their concern about refill dates and provide greater flexibility on how refill is determined, taking into consideration the range of potential impacts, to support potential amendment proposals to relevant Water Management Plans.

Chapter 8

Fiscal Pressures and Capacity Issues

The efficiency and effectiveness of the existing approval processes and associated policies and technical requirements could be limited by Ontario's overall fiscal reality and capacity issues facing provincial ministries, municipalities, and conservation authorities.

8.1 Ontario's Deficit

Ontario's deficit was estimated to be as high as \$15 billion in 2018 leading to the government committing to taking necessary steps towards restoring Ontario's fiscal health. Ontario's deficit places pressure on the Province to further reduce costs and promote economic growth to help balance the budget and sustainably fund essential public services for current and future generations.

8.2 The Ministry of Natural Resources and Forestry Capacity

Some stakeholders and other groups have raised concerns regarding the capacity of the MNRF to support approval processes and associated policies and technical requirements.

The MNRF has not assessed internal capacity needs required to support provincial natural hazard management policies and programs or assessed how such programs are resourced in other jurisdictions. The Environmental Commissioner of Ontario has also raised concerns that reductions in budgets, staffing and in-house expertise has hampered the effectiveness of the MNRF.

8.3 Conservation Authority Capacity

Many MNRF policies and programs associated with protecting Ontarians from flooding and other natural hazards are delivered by conservation authorities. Reliance on conservation authorities to administer permit applications and decisions, and to comment on municipal planning policies reduces costs for the MNRF but increases costs for conservation authorities and the municipalities that fund them.

Capacity levels among conservation authorities are very diverse with annual budgets ranging from less than \$1 million to more than \$100 million. This divergence in capacity affects the extent to which any given conservation authority can support hazard management policy objectives. Increases to conservation authority roles and responsibilities disproportionately impact smaller conservation authorities with limited

tax bases within their jurisdictions to support program and service delivery. Conservation Ontario and municipalities have repeatedly requested increases to provincial funding levels to conservation authorities, which have not been increased in over 20 years, and this year they have requested that the 2018 funding level be reinstated.

8.4 Municipal Capacity

The MNRF relies on municipalities to implement natural hazard policies contained within the Provincial Policy Statement (PPS).

As with conservation authorities, capacity levels among municipalities are also quite diverse. Small, rural municipalities typically have a much smaller tax base than larger urban municipalities, and may be less able to support the effective management of flooding and other natural hazards.

Some municipalities rely on conservation authorities to support the management of flooding and other natural hazards, and would not have the resources to take on these responsibilities.

Recommendation #66

That the Province maintain, at a minimum, the current level of funding in departmental budgets and programs related to everything flood (i.e. existing approval processes and associated policies and technical requirements, floodplain mapping, maintenance of flood infrastructure, satellite imagery, etc.).

Appendix A – List of Documents Reviewed

A number of reports and additional background information was reviewed in developing recommendations included in this report, many of which were provided by stakeholders and individuals via email or during in-person meetings. Appendix B – Community Tours

Community tours were held from September 4 – 14, 2019. The tour was broken into two sessions as noted below. The sessions were designed to allow municipal leaders and other stakeholders to share their experiences with flooding and their ideas as to how the province can be better prepared in the future.

Feedback provided during the tour was used to assist in developing recommendations. Of note, both sessions included engagement sessions (held in groups), targeted engagement session (one-on-one meetings), and area-specific tours to help gain a complete understanding of the issues and impacts Ontarians are facing as a result of this spring's flooding.

Community Tour Session #1 – Eastern Ontario

- Wednesday September 4, 2019 – Ottawa (*targeted session and tour*)
 - Britannia
- Thursday September 5, 2019 – Ottawa (*engagement session and tour*)
 - Constance Bay, Braeside, Rhoddy's Bay and Westmeath
- Friday September 6, 2019 – Pembroke (*engagement session and tour*)
 - Pembroke, Deux Rivieres, Klock and Mattawa
- Saturday September 7, 2019 – North Bay (*engagement session*)

Community Tour Session #2 – Central and Southwestern Ontario

- Tuesday September 10, 2019 – Toronto (*targeted meeting and tour*)
 - Rockcliffe neighbourhood and Port Lands
- Wednesday September 11, 2019 – Huntsville (*engagement session and tour*)
 - Bracebridge
- Thursday September 12, 2019 – Toronto (*targeted sessions*)
- Friday September 13, 2019 – Cambridge (*engagement session and tour*)
 - Cambridge Flood Walls, Brantford Flood Works and Eagle Place
- Saturday September 14, 2019 – London (*engagement session*)

Appendix C – Engagement Session Participation

The following is a list of organizations that participated in Regional Engagement Sessions.

Thursday September 5, 2019 – Ottawa Engagement Session

City of Clarence-Rockland

City of Ottawa

MPP, Carlton

MPP, Constance Bay / Kanata-Carlton

Mississippi Valley Conservation Authority

Rideau Valley Conservation Authority

South Nation Region Conservation Authority

Town of Mississippi Mills

Township of Champlain

Township of Alfred and Plantagenet

Friday September 6, 2019 – Pembroke Engagement Session

City of Pembroke

Municipality of Hastings Highlands

MP, Renfrew–Nipissing–Pembroke

Town of Arnprior

Town of Deep River

Township of Admaston/Bromley

Township of Brudenell, Lyndoch and Raglan

Township of Greater Madawaska

Township of Laurentian Valley

Township of Madawaska Valley

Township of McNab/Braeside

Township of North Algona Wilberforce

Township of Whitewater Region

Saturday September 7, 2019 – North Bay Engagement Session

City of North Bay

City of Temiskaming Shores

MPP, Nipissing

Municipality of East Ferris

Municipality of French River

Nipissing First Nation

North Bay-Mattawa Conservation Authority

Public Services and Procurement Canada

Town of Mattawa
Township of Chisholm
Township of Mattawan

Wednesday September 11, 2019 – Huntsville Engagement Session

Armour Township
MPP, Parry Sound-Muskoka
Muskoka Watershed Advisory Group
Muskoka Watershed Council
Town of Bracebridge
Town of Gravenhurst
Town of Huntsville
Town of Lake of Bays
Town of Muskoka Lakes
Township of Algonquin Highlands
Ryerson Township
Village of Burk's Falls

Friday September 13, 2019 – Cambridge Engagement Session

City of Brantford
City of Cambridge
City of Kitchener
City of St. Catharines
County of Brant
Grand River Conservation Authority
Halton Region Conservation Authority
MPP, Cambridge (Office of)
MPP, Haldimand-Norfolk (Office of)
Region of Waterloo

Saturday September 14, 2019 – London Engagement Session

City of Sarnia
County of Essex
Essex Region Conservation Authority
Lower Thames Valley Conservation Authority
Municipality of Chatham-Kent
Town of Essex
Town of Kingsville
Township of Pelee
St. Clair Region Conservation Authority

Upper Thames River Conservation Authority

The following is a list of the individuals and groups who met directly with the Special Advisor.

Wednesday September 4, 2019

Ottawa River Regulation and Planning Board

Thursday September 5, 2019

Insurance Bureau of Canada
International Joint Commission

Friday September 6, 2019

Westmeath Citizens Group

Saturday September 7, 2019

North Bay-Mattawa Conservation Authority

Tuesday September 10, 2019

Toronto and Region Conservation Authority

Thursday September 12, 2019

Association of Municipalities of Ontario
City of Toronto
Electrical Safety Authority
Emergency Management Ontario
Great Lakes Collaborative
Kingdom of the Netherlands
MPP Lindsey Park, Durham
Regional Public Works Commissioners of Ontario

Friday September 13, 2019

Intact Centre on Climate Adaptation
Grand River Conservation Authority

Saturday September 14, 2019

Upper Thames River Conservation Authority

Appendix D – Written Submissions to the Special Advisor on Flooding

Written submissions were also received from a number of different groups over the course of the review. The submissions covered an array of issues including introductory comments, follow up materials, invitations/requests to meet with Mr. McNeil, detailed comments about flooding, water management and recent flood experiences or ideas of recommendations that should be put forward to government.

The list below identifies who submitted comments. A number of submissions were also received from members of the public whose names are not included below.

- Aquanty Inc.
- Association of Municipalities of Ontario
- Blue Mountain Watershed Trust
- Boating Ontario Association
- Central Lake Ontario Conservation Authority
- Cheryl Gallant, MP Renfrew-Nipissing-Pembroke
- City of Ottawa
- Community Living Upper Ottawa Valley
- Conservation Ontario
- County of Essex
- Electrical Safety Authority
- Emergency Management Ontario
- Great Lakes Collaborative
- Insurance Brokers Association of Ontario
- International Joint Commission
- International Joint Commission, Great Lakes-St. Lawrence Adaptive Management Committee
- Kingdom of the Netherlands
- Marit Stiles, MPP, Davenport
- McMaster University
- Ministry of the Environment, Conservation and Parks
- Ministry of Infrastructure
- Ministry of Municipal Affairs and Housing
- Ministry of Natural Resources and Forestry
- Municipality of Chatham-Kent
- Municipality of Clarington
- Municipality of Leamington
- Muskoka Lakes Association

- Muskoka Watershed Council
- North Bay-Mattawa Conservation Authority
- Ontario Association of Home Inspectors
- Ontario Power Generation
- Ottawa River Regulation Planning Board
- Regional Public Works Commissioners of Ontario
- Toronto and Region Conservation Authority
- Township of Champlain
- Township of Laurentian Valley
- Township of Madawaska Valley
- Upper Thames River Conservation Authority
- Upper Trent Water Management Partnership
- Westmeath Citizens Group
- World Wildlife Fund
